## Supplementary Material

# A new six-coordinate organotin(IV) complex of $\mathrm{OP}\left[\mathrm{NC}_{5} \mathrm{H}_{10}\right]_{3}$ : a comparison with an analogous five-coordinate complex by means of X-ray crystallography, Hirshfeld surface analysis and DFT calculations 

ATEKEH TARAHHOMI* and ARIE VAN DER LEE

## Hirshfeld surface analysis:

The survey Hirshfeld surfaces show that H...H contacts in both $\mathbf{1}$ and IZOVIE are majority in the intermolecular interactions covering $90.8 \%$ and $75.9 \%$ of the total HS, respectively, where visible red spots on the HS of $\mathbf{1}$ are related to these H...H interactions while for IZOVIE not any red spot on the surface is found for such interactions. These H...H contacts are recognized by the points spread out in the center of FP providing the closest contacts. For 1, these closest contacts are manifested by a short sharp spike on the diagonal plot. Moreover, color change from blue to green in the regions of $d_{\mathrm{e}}=d_{\mathrm{i}}(\approx 1.0-1.7 \AA$ for $\mathbf{1}$ and $1.2-1.7 \AA$ for IZOVIE) on the plot diagonal indicates an increase of the occurrence frequency for $\mathrm{H} \ldots \mathrm{H}$ contacts.

Besides the $\mathrm{H} \ldots \mathrm{H}$ contacts, the presence of intermolecular interactions of type $\mathrm{C}-\mathrm{H} \ldots \mathrm{Cl}$ in the crystal structures is evident by the $\mathrm{H} . . . \mathrm{Cl} / \mathrm{Cl} . . \mathrm{H}$ FPs which comprise $9.1 \%$ of the total HS for 1 and $23.0 \%$ for IZOVIE (for example: $\mathrm{C} 10-\mathrm{H} 10 \mathrm{~B} \ldots \mathrm{Cl} 2, \mathrm{C} 10 \ldots \mathrm{Cl} 2=3.821$ (2) $\AA$, $\angle \mathrm{C} 10-\mathrm{H} 10 \mathrm{~B}-\mathrm{Cl} 2=152.8^{\circ}$ and symmetry code: $x-\frac{1}{2},-y+\frac{1}{2}, z-\frac{1}{2}$ in IZOVIE). The related regions on HSs are represented as points in the regions of bottom right $\left(d_{\mathrm{e}}<d_{\mathrm{i}}, \mathrm{Cl} \ldots \mathrm{H}\right)$ and top left $\left(d_{\mathrm{e}}>d_{\mathrm{i}}, \mathrm{H} \ldots \mathrm{Cl}\right)$ on the corresponding plots. For IZOVIE, these regions are characterized as two wings with sharp tips, including some points scattered in the center of plot.

As mentioned above, in 1, red spots on the HS are only related to H...H contacts, whereas for IZOVIE, only two large red spot are visible on the HS which can be assigned to $\mathrm{Sn} . . . \mathrm{Cl} / \mathrm{Cl}$... Sn contacts ( $\mathrm{Sn} 1 \ldots \mathrm{Cl} 2=3.2799$ (6) $\AA$; symmetry code: $-x+1,-y+1,-z$ ) with a characteristic shape as two thin boomerangs that are symmetric with respect to the diagonal of the plot in the
$\mathrm{Sn} \ldots \mathrm{Cl} / \mathrm{Cl} \ldots \mathrm{Sn}$ FP (figure 4). These contacts include minimum $d_{\mathrm{i}}+d_{\mathrm{e}}$ value of about $3.3 \AA$ which comprises $1.0 \%$ of the entire HS.

## Vibrational analysis

For 1, the highest experimental wavenumbers at $2962 \mathrm{~cm}^{-1}$ (calculated in the range $3187 \mathrm{~cm}^{-1}$ to $3197 \mathrm{~cm}^{-1}$ ) and $2847 \mathrm{~cm}^{-1}$ (calculated: 3069 and $3070 \mathrm{~cm}^{-1}$ ) are assigned to $\mathrm{C}-\mathrm{H}$ asymmetric and symmetric stretching vibrational modes for $\mathrm{CH}_{3}$ group in the $\mathrm{Cl}_{2} \mathrm{Sn}\left(\mathrm{CH}_{3}\right)_{2}$ group, respectively. The wavenumbers $2918 \mathrm{~cm}^{-1}$ and $2768 \mathrm{~cm}^{-1}$ correspond to the same modes for $\mathrm{CH}_{2}$ groups in the piperidine rings with theoretical values in the range $2982 \mathrm{~cm}^{-1}$ to $3147 \mathrm{~cm}^{-1}$. The bending (scissoring) modes are observed at $1452 \mathrm{~cm}^{-1}$ for $\mathrm{CH}_{2}$ groups and at $1354 \mathrm{~cm}^{-1}$ (asymmetric mode) and $1233 \mathrm{~cm}^{-1}$ (symmetric) for $\mathrm{CH}_{3}$ groups. This assignment is supported by the theoretical results in the range $1500 \mathrm{~cm}^{-1}$ to $1554 \mathrm{~cm}^{-1}$ for $\mathrm{CH}_{2}$ and in the range 1484 to $1495 \mathrm{~cm}^{-1}$ (asymmetric) and $1265,1266,1275 \mathrm{~cm}^{-1}$ (symmetric) for $\mathrm{CH}_{3}$. The $\mathrm{CH}_{2}$ bending vibrational modes in the piperidine rings including wagging (experimental: $1304 \mathrm{~cm}^{-1}$, calculated: in the range $1372 \mathrm{~cm}^{-1}$ to $1422 \mathrm{~cm}^{-1}$ ), twisting (experimental: $1259 \mathrm{~cm}^{-1}$, calculated: $1292 \mathrm{~cm}^{-1}$ to $1357 \mathrm{~cm}^{-1}$ ) and rocking (experimental: $1157 \mathrm{~cm}^{-1}$, calculated: $1152 \mathrm{~cm}^{-1}$ to $1191 \mathrm{~cm}^{-1}$ ) are observable. However, the medium (m) or weak (w) bands in $870(\mathrm{~m}), 783(\mathrm{~m})$ and 613 (w) $\mathrm{cm}^{-1}$ for the $\mathrm{CH}_{2}$ rocking modes are also observed besides the strong band at $1157 \mathrm{~cm}^{-1}$. The experimental frequency for the stretching vibrational mode of $\mathrm{P}=\mathrm{O}$ bond is $1115 \mathrm{~cm}^{-1}$ compared to the theoretical value at $1001 \mathrm{~cm}^{-1}$. The various stretching and bending vibrational modes relative to the piperidine rings are found in the range $916 \mathrm{~cm}^{-1}$ to $1136 \mathrm{~cm}^{-1}$ appearing as five bands in IR spectrum (table 4) which are confirmed by the calculated values in the range $915 \mathrm{~cm}^{-1}$ to $1147 \mathrm{~cm}^{-1}$. The PN stretching vibrational modes besides the stretching modes of rings appear as a strong band at $964 \mathrm{~cm}^{-1}$ and a medium band at $731 \mathrm{~cm}^{-1}$ supported by the calculated data in the range $952 \mathrm{~cm}^{-1}$ to $964 \mathrm{~cm}^{-1}$ (for the former) and $634 \mathrm{~cm}^{-1}$ to $698 \mathrm{~cm}^{-1}$ (for the latter). A medium strong band at $845 \mathrm{~cm}^{-1}$ represents the vibrational rocking mode of $\mathrm{CH}_{3}$ groups corresponding to the calculated values in the range 836 to $865 \mathrm{~cm}^{-1}$. The medium strong
bands at $575 \mathrm{~cm}^{-1}$ (calculated: $562 \mathrm{~cm}^{-1}$ ) and $498 \mathrm{~cm}^{-1}$ (calculated: $491 \mathrm{~cm}^{-1}$ ) point to asymmetric and symmetric stretching vibrations of the $\mathrm{Sn}-\mathrm{C}$ bonds, respectively. The ring deformation mode at $478 \mathrm{~cm}^{-1}$ (calculated: $450 \mathrm{~cm}^{-1}$ ) as a medium band is as well distinguishable in the experimental IR spectrum.

As is seen in table 4, for IZOVIE similar calculated results are obtained in which the number of the calculated frequencies is halved relative to $\mathbf{1}$ as is expected by the presence of only one ligand in IZOVIE versus two in 1.

Table S1. Vibrational assignments of experimental FT-IR frequencies of $\mathbf{1}$ along with corresponding theoretical vibrational data $\left(\mathrm{cm}^{-1}\right)$ at B3LYP/SDD level for $\mathbf{1}$ and IZOVIE.
