Data Mining in Manufacturing: A Review Based on the Kind of Knowledge

A. K. Choudhary¹, M. K. Tiwari² and J. A. Harding^{1*}

Abstract

In modern manufacturing environments, vast amounts of data are collected in database management systems and data warehouses from all involved areas, such as product and process design, assembly, materials planning, quality control, scheduling, maintenance, fault detection and so on. Data mining has emerged as an important tool for knowledge acquisition in manufacturing databases. This paper reviews the literature dealing with knowledge discovery and data mining applications in the broad domain of manufacturing with an special emphasis on the type of functions to be performed on data. The major data mining functions to be performed include characterization and description, association, classification, prediction, clustering and evolution analysis. The papers reviewed have therefore been categorized in these five categories. It has been shown that there is a rapid growth in the application of data mining in the context of manufacturing processes and enterprises in the last 3 years. This review reveals the progressive applications and existing gaps identified in the context of data mining in manufacturing. A novel text mining approach has also been applied to the abstracts and keywords of 150 identified literatures to identify the research gaps and find the linkages between knowledge area, knowledge type and data mining tools and techniques applied.

I. INTRODUCTION

Knowledge provides power in many manufacturing context enabling and facilitating the preservation of valuable heritage, learning new things, solving intricate problems, creating core competencies and initiating new situations for both individuals and organizations now and in the future [1]. In most sectors, manufacturing is extremely competitive and the financial margins that differentiate between success and failure are very tight, with most established industries needing to compete, produce and sell at a global level. To master these trans-continental challenges, a company must achieve low cost production yet still maintain highly skilled, flexible and efficient workforces who are able to consistently design and produce high quality, low cost products. In higher-wage economies, this can generally only be done through very efficient exploitation of knowledge[2-3]. However knowledge can take many forms and it is necessary to identify the kind of knowledge to be mined when examining the huge amount of data generated during manufacturing.

In modern manufacturing, the volume of data grows at an unprecedented rate in digital manufacturing environments, using barcodes, sensors, vision systems etc. These data may be related to design, products, machines, processes, materials, inventories, maintenance, planning and control, assembly logistics, performances etc and may include patterns, trends, associations and dependencies. However, the use of accumulated data has been limited, which has led to the “rich data but poor information” problem [4]. The collected manufacturing data contains valuable information and knowledge that could be integrated within the manufacturing system to improve decision making and enhance productivity [5].

The huge amounts of data in manufacturing databases, which contain large numbers of records, with many attributes that need to be simultaneously explored to discover useful information and knowledge, make manual analysis impractical. All these factors indicate the need for intelligent and automated data analysis methodologies, which might discover useful knowledge from data. Knowledge discovery in databases (KDD) and data mining (DM) become extremely important tools in realizing the objective of intelligent and automated data analysis. Data mining is a particular step in the process of KDD, involving the application of specific algorithms for extracting patterns (models) from data. The additional steps in the KDD process, such as data preparation, data cleaning, data selection, incorporation of appropriate prior knowledge and proper interpretation of the results of mining, ensure that useful knowledge is derived from data[6].

KDD incorporates theories, algorithms and methods from the intersection of several research fields including database technology, machine learning, statistics, artificial intelligence, knowledge based systems and data visualization. A natural question that arises is how is KDD different from other fields such as machine learning or artificial intelligence or related fields? The answer is that these fields provide specific data mining tools that can be used in various steps of a KDD process. Recently, with the growth of data mining technology, researchers and practitioners of various aspects of manufacturing and logistics have started applying this technology to search for hidden relationships or patterns which might be used to equip the system with new knowledge. Early applications of data mining were mostly applied to financial applications. Zhang and Zhou [7] described data mining in the context of financial applications from both technical and application perspectives. In this area, the competitive advantage gained through data mining included increased revenue, reduced cost, much improved market place responsiveness and awareness. A recent survey carried out by Harding *et al.*[8] and a special issue published on “Data Mining and applications in Engineering design, manufacturing and logistics”[9] clearly indicated the potential scope of data mining in these areas to achieve the competitive advantages. A major advantage of data mining over other experimental technique is that the required data for analysis can be collected during the normal operation of the manufacturing process being studied. Therefore, it is generally not necessary to specially dedicate machines or processes for data collection.

The diversity of data mining tools, techniques and functionalities provides great opportunities on the one hand, but on the other hand the profusion of options cause confusion. Han and Kamber [10] classified data mining systems based on various criteria such as *kind of database mined, kind of knowledge mined, kind of technique utilized, application area adapted*. Pham and Afify [11] reviewed machine learning techniques in the manufacturing domain. They evaluated the several machine learning techniques and examined application areas in which they have been successfully deployed. Harding *et al.* [8] surveyed data mining systems in different application area of manufacturing, including less considered areas such as manufacturing planning and shop floor control. Over the decades, data mining has been applied in various but limited aspects of manufacturing and logistics domains. However, in the last few years, data mining research in manufacturing has increased at an exponential rate. In the last 3 years approximately 75 papers have been published, which is 50% of the relevant literature identified and reviewed in this paper.

Han and Kamber [10] mentioned that the kind of knowledge to be mined determines the data mining functions to be performed. The kind of knowledge include *concept description (characterization and discrimination), association, classification, clustering, and prediction*. The aim of this paper is therefore to consolidate the existing state-of-the art research efforts concerning the current practices in data mining applications in manufacturing based on the *kind of knowledge mined* and *kind of technique* utilized, thereby identifying promising areas for study. This paper also identifies the most utilized techniques for mining certain types of knowledge. To identify this, a novel Text Mining(TM) approach has been applied on the abstracts of 150 papers. The results identify the research gaps, and show the linkages between *Knowledge area, knowledge mined and kind of technique used to mine data in the manufacturing domain*.

The remainder of the paper is organized as follows: The next section briefly discuss about KDD, data mining, and kinds of knowledge particularly in manufacturing contexts. Section 3 will discuss concept descriptions which includes characterization and discrimination in manufacturing. Classification in manufacturing is discussed in section 4, followed by clustering in manufacturing in section 5. Section 6 discusses prediction in manufacturing. Association in manufacturing is discussed in section 7. A novel text mining approach has been applied on abstracts and keywords of reviewed literature to identify the research gaps and identify the linkages between knowledge area, knowledge mined and techniques used, and this is followed by conclusions in section 9.

2. KDD, DATA MINING and KNOWLEDGE TYPES

2.1 Basic Definitions

KDD is the nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data [12]. Data mining is a particular step in this process, involving the application of specific algorithms for extracting patterns(models) from data. The additional steps in the KDD process, such as data preparation, data selection, data cleaning, incorporation of prior knowledge, and proper interpretation of the results of mining ensures that useful knowledge is derived from the data. An important notion *interestingness* is usually taken as an overall measure of pattern value, combining validity, novelty, usefulness, simplicity and understandability. As a matter of fact, knowledge in this definition is purely user oriented and domain specific and is determined by whatever function and threshold the user chooses. The role of interestingness is to threshold the huge number of discovered patterns and report only those which may be of some use.[13].

2.2 KDD Process in Manufacturing

The overall KDD process applied in manufacturing is delineated in Figure 1. The KDD process is interactive and iterative involving more or less the following steps [14,6].

- I. Understanding the manufacturing domain: This includes the relevant prior knowledge related to manufacturing application and targeted goal.
- II. Collecting the targeted data: This includes the collection of raw data, selecting the data set and focussing on the set of variables affecting the manufacturing problem.
- III. Data cleaning, pre-processing and transformation: This includes the pre-processing of data such as noise removal, missing value replacement and data cleaning. Data are consolidated into forms appropriate for mining.
- IV. Data Integration: This includes integrating the multiple manufacturing heterogeneous data sources.
- V. Choosing the functions of data mining: Based on the kind of knowledge required, various data mining functions (clustering, classification, prediction, association, regression, summarization etc.) need to be performed to derive the model. Choosing the appropriate data mining algorithm: This includes the selection of techniques to perform the desired function to find the patterns in the data.
- VI. Choosing the appropriate data mining algorithm. This includes searching for patterns of interest in a particular representational form or a set of such representations.
- VII. Interpretation and Visualization: This includes the interpretation and visualization of patterns to derive novel knowledge.
- VIII. Implementation of discovered knowledge: The discovered knowledge is incorporated into the manufacturing domain performance system. Feed back is received and the knowledge can be modified further based on feedback.
- IX. Knowledge storage, reuse and integration into manufacturing system: This includes the storage of discovered knowledge for further reuse and possible integration in to the manufacturing system.

Figure1. Knowledge Discovery and Data Mining in Manufacturing Systems Environment

2.3 Data Mining in Manufacturing:

Data mining is an interdisciplinary field with the general goal of predicting outcomes and uncovering relationships in data. It makes use of automated tools and techniques, employing sophisticated algorithms to discover hidden patterns, associations, anomalies and/or structure from large amounts of data stored in a data warehouse or other information repositories. In the context of manufacturing, two high level primary goals of data mining are prediction and description. Descriptive data mining focuses on discovering interesting patterns to describe the data. Predictive data mining focuses on predicting the behaviour of a model and determining future values of key variables based on existing information from available databases. The boundaries between, descriptive and predictive data mining are not sharp, e.g. some aspects of the predictive model can be descriptive, to the degree that they are understandable, and vice versa. The goals of prediction and description can be achieved by using a variety of data mining tools and techniques.

2.4 Kind of Knowledge to be mined

As explained in the introduction, before performing a data mining task in manufacturing, it is necessary to identify the kind of knowledge to be mined. Kind of knowledge mined determines the data mining functions. The next section therefore describes a range of functions and reviews their applicability in manufacturing domains.

3. CONCEPT DESCRIPTION (CHARACTERIZATION AND DISCRIMINATION) IN MANUFACTURING

Descriptive data mining describes the data set in a concise and summarative manner and presents interesting general properties of data. In most of manufacturing problems, it is necessary to view the summarized data in concise, descriptive terms to provide an overall picture of the manufacturing domain's data or distinguish it from a set of comparative classes. This type of data mining is called concept description and includes characterization and discrimination. For example in PCB manufacturing quality control problems, it is necessary to identify the various features that cause defects. Characterization can be used to identify the features that significantly impact the quality. Characterization provides a concise and succinct summarization of the given collection of data, while concept of class discrimination or comparison provides descriptions that compare two or more collections of data. In manufacturing contexts, these functions are basically used to understand the process.

Tseng *et al.* [15] developed an extended rough set theory based on an approach to solve the quality control (QC) problem of Printed Circuit Board (PCB) manufacturing. The algorithm is able to derive the rules and identify the most significant features to solve the QC problems. The derived rules from the dataset provide an indication of how to best investigate the problem further. Unnatural control chart patterns (CCP) are associated with a particular set of assignable causes for process variation. Guh [16] presented a hybrid neural network and decision tree based model to detect and discriminate typical unnatural CCPs, while identifying the major parameters and starting point of the CCP detected. Fountain *et al.* [17] described a decision theoretic approach to Die Level Functional Test (DLFT) in which historical test data from IC products of *Hewlett Packard* company are mined to create a probabilistic model of patterns for die failure. This model is combined with greedy value-of-information computation to decide in real time, which die to test next and when to stop testing. The KDD process is basically a user driven task but the user driven approach are not efficient enough for use in manufacturing. Neaga and Harding [18] presented a framework for the integration of complex enterprise applications including data mining systems. The presented approaches provide the definition and development of a common knowledge enterprise model, which represents a combination of previous projects on manufacturing enterprise architectures and Object Management Group (OMG) models and standards related to data mining

Kusiak and Kurasek [19] applied a rough set theory based data mining approach to identify the cause of solder defects in a PCB. The rules derived from the dataset provide a robust

indication of where the solder is too narrow, and thereby make more effective further investigations into the cause of solder ball defects. Lee and Ng [20] presented a hybrid case based reasoning (Hy-Case) based system for online technical support of PC fault diagnosis. Hy-Case consists of a natural language (keyword) as input and the graph theoretic constraint-net. Romanowski and Nagi [21] applied a decision tree based data mining approach on a scheduled maintenance dataset and a vibration signal dataset. Subsystems which are most responsible for low equipment availability are recognized in the scheduled maintenance data, and a recommendation for preventive maintenance interval is made. The vibration data is analyzed to find the sensors and frequency responses which give the most information about the type of fault present in the equipment. Decision tree has proved to be the valuable tool for description, generalization and classification. Murthy [22] surveyed its applicability in various domains and identified the important issues involved. They concluded that the hierarchical tree construction methodology is very powerful and it has repeatedly been shown to be useful for diverse real world problem.

Menon *et al.* [23] analyzed the product development process based on a textual database using data mining to deliver the right information at the right time to satisfy particular needs. The data mining tools were applied on product development process data to provide quick and reliable feedback that would facilitate faster product development. Huyet [24] proposed a evolutionary optimization and data mining based approach to produce the knowledge of systems behaviour in a simulated job shop based production process. Holden and Serearuno[25] developed *iGem*, an artificial intelligence tool that integrates rule based knowledge representation, fuzzy logic and genetic algorithms to produce a system for automating and introducing consistency into the grading of diamonds and gemstones. It derives the knowledge from repeated examples of previously corrected graded stone and improves its performance by learning from experience.

Assigning proper dispatching rules is an important issue in enhancing the performance measures for a flexible manufacturing system (FMS). Liu *et al.*[26] presented SAMA (supervised attribute mining algorithm) which is based on the fuzzy set theoretic approach and GA for the attribute selection problem of dispatching rules. Li *et al.* [27] improved the accuracy of FMS scheduling for small datasets, as at the early stage of manufacturing only a few data points can be obtained. Their study develops a data trend estimation technique and combines it with mega-fuzzyfication and an adaptive network based fuzzy inference system (ANFIS). Li and Olafsson [28] introduced a novel methodology for generating scheduling

rules using data mining. This approach includes pre-processing of historic scheduling data into an appropriate data file, discovery of key scheduling concepts, and represents the results of data mining so that they can be used for job scheduling. Koonce and Tsai [29] applied data mining methodologies to explore the patterns in data generated by a GA performing scheduling operations and to develop a rule set scheduler which approximates the GA's scheduler. The Attribute Oriented Induction approach was used to characterize the relationship between operations' sequences and their attributes. Knowledge generated from data mining can be used to analyze the effect of decisions made at any stage. Belz and Mertens [30] used SIMULEX coupled with a knowledge based system to model the plant and evaluate the results of various rescheduling measures. They used MANOVA for statistical analysis, and the collected data is analysed to identify normal and abnormal patterns. Maki *et al.* [31] developed an intelligent system in Hitachi for online data analysis using a data mining approach. Their approach consists of three step feature extraction, combinatorial search and presentation. They have applied this method to LSI fault analysis and found that data mining is useful for indicating to engineers where to focus their attention when looking for faults. Subsequently a similar methodology has been applied on quality control of production process[32].

Caskey [33] developed a general environment for providing the right knowledge to achieve a specific factory condition at the right time. In addition to discrete event simulation, he used GAs and neural networks in identifying the structure of the data. The knowledge extracted was in the form of “actual control applied → performance obtained” and the knowledge generated could be used to increase the accuracy of the system or validate the performance model. A rough set theory based approach was used by Shen *et al.* [34] to get the final reducts and extract the rules for fault diagnosis of diesel engines. These rules were used to distinguish the fault type or to inspect the dynamic characteristics of the machinery. For ceramics manufacturing, Dengiz *et al.* [35] presented a two stage data-mining approach to accurately estimate flaw distribution. First stage of data mining is image processing for automatic identification and recovery of large flaws from noisy microscopic images. The second stage is to use the flaw information to fit the extreme value distribution function. These provides a better understanding for manufacturer and designers about the processing method. Jung *et al.* [36] proposed vertical group wise threshold (VGWT) procedure for the multiple high dimensional functional data. Here the “Functional Data” refers to the analogue or digital signal measured during each operational cycle of a manufacturing process. The proposed methodology increases the class separability with a reasonably small loss in data reduction efficiency. Hou and Yang [37] presented a data model and technology mining

model to investigate the technology categories with more return and client demand in Technology and Service Provider (TSP) environment. The proposed model can be used to derive suggestions including the critical issues such as technology development, return of technology, R&D investment and outreach sequence of technology.

Data mining has proved to be important for yield improvement which is a key element to ensure the profitability of semiconductor manufacturing. Bergeret and Gall [38] applied a Bayesian network to solve yield issues, where the root cause comes from a failure at a single process stage. Three different methods SPC technique, DOE and Bayesian network have been applied to resolve 2 critical yield issues (a) faulty batch of raw material and (b) process change. The advantage of this approach is that the only data required are the process dates of the lots at each process stage and the probe results. Dabbas and Chen [39] presented an integrated relational database approach for modelling and collecting semiconductor manufacturing data from a multi-database system and transforming the data into useful reports. These reports are utilized to monitor the performance of one of Motorola's wafer fabs by tracking different key metrics and in turn improving the factory performance. A French truck manufacturer applied KDD techniques on the datasets of measures recorded during the test of diesels manufactured at their production lines. By analyzing the data, they significantly (about 25%) reduced the processing time [40]. Similarly, at Dofasco, a fully integrated Canadian Steel manufacturer applied multivariate statistical analysis to several steel production processes to improve the productivity and reduce maintenance costs[41]. This provided production engineers and operators with useful and easy to understand results. Batanov *et al.* [42] researched knowledge-based maintenance systems and developed a prototype system called EXPERT-MM, which works on historical failure data and provides suggestions for an appropriate preventive maintenance schedule. Chen *et al.* [43] applied hyperspace data mining in materials manufacturing. Master Miner is provided with several algorithms to provide better understanding of materials design and manufacturing.

From this review, the main areas where data mining is used for concept description (characterization and discrimination) include fault diagnostics, scheduling, dispatching, maintenance and manufacturing process. The next section will describe classification, which is another functionality performed on manufacturing data.

4. CLASSIFICATION IN MANUFACTURING

Classification is a useful functionality in many areas of manufacturing, for example, in semiconductor industry, defects are classified to find patterns and derive the rules for yield improvement. Online control chart pattern recognition is another example of classification for statistical process control, because, unnatural patterns displayed by control chart can be associated with specific causes that adversely impact the manufacturing process.

Classification is a learning function that maps (classifies) a data item into one of several predefined categorical classes. Generally, it is performed in two steps. In the first step, a model is built describing a predetermined set of data classes or concepts. The model is constructed by analyzing the database tuples described by attributes. The data tuples analyzed to build the model collectively form the training dataset. This step is also known as supervised learning as the class label of each training sample is provided. The learned model is represented in the form of classification rules, decision trees, or mathematical formulae. In the second step, based on classifier accuracy, the model is used for classification of the future data or test data. General techniques used for classification are decision tree induction, Bayesian classification, Bayesian belief network and neural network. Other techniques such as K Nearest neighbour, case based reasoning, GA, Rough Set Theory, fuzzy logic and various hybrid methods are also used for classification purpose[10].

Knowledge acquisition is a well known problem in building expert systems. In one of the earliest applications, Irani *et al.*[44] developed an expert system for diagnosis and process modelling of semiconductor manufacturing that uses a generalized ID3 (GID3) based machine learning technique for knowledge acquisition. The discovered pattern is consistent with the data and conformed with the engineers' expectations. GID3 has been used for classification purposes in the areas which were targeted for automation by the semiconductor Research Corporation, a consortium of US semiconductors manufacturers. McDonald [45] discussed the applicability of data mining in inline inspection and control, and automatic defect classification. He made a proposal to extend these tools to improvement of reliability of products during wafer fabrication, packaging and final testing steps. Braha and Shmilovici [46] presented three classification based data mining methods (decision tree induction, neural network and composite classifier) for a new laser based wafer cleaning process called advanced wafer cleaning. The purpose of the data mining based classifier is to enhance the understanding of the cleaning process by categorizing the given data into a given predefined number of categorical classes and determine to which the new data belong.

False recognition/incorrect classification is a frequently encountered issue in the Control Chart Pattern recognition. In this regard, Guh [47] presented a hybrid learning based system that integrates neural network and decision tree learning to overcome the CCP Classification problem in real time. This hybrid system consists of three sequential modules namely feature extraction, coarse classification and fine classification. It outperformed the conventional approaches in terms of recognition speed and accuracy. Rokach and Maimon [48] applied feature set decomposition methodology for quality improvement. They developed the Breadth Oblivious Wrapper (BOW) algorithm and showed its superiority over existing tools on datasets from IC fabrication and food processing. The idea is to find the classifier that is capable of predicting the quality measure of product or batch based on its manufacturing parameters. Skormin *et al.* [49] presented a classification model for the database containing the information downloaded from a dedicated monitoring system of flight critical hardware. A decision tree based data mining model has been used for the accurate assessment of the probability of failure of any avionics unit by utilizing historical data relating to environment and operation condition.

Extensive research has been carried out in developing knowledge based condition monitoring systems. To deal with noise, uncertainty and decrease the rate of misclassification, Peng [50] proposed a hybrid Fuzzy-inductive learning based approach. This method has been successfully deployed in diagnosing the conditions of a tapping process. The results showed that the accuracy of classification is better than traditional inductive learning method. Pasek [51] explored a rough set theory based classifier for cutting tool wear monitoring applications. But, this method is only applicable to offline situations. For online monitoring, Hou *et al.* [52] integrated the neural network and rough sets for manufacturing process monitoring and fault diagnosis. A neural network was used to classify the quality faults such as wrinkles and uneven thickness. Apart from providing operating guidelines, rough set is used to determine the causal relationship between parameters like process temperature and output quality measures. In the extension of this work, fuzzy set theory with the fuzzy variable rough set approach have been used[53]. The results showed that the proposed approach was robust and able to deal with noisy data and produced better rules.

As data sets increase in size, exploration, manipulation and analysis become more complicated and resource consuming. To deal with these situations, Jeong *et al.* [54] proposed a data compression and data denoising method, which was used with tree based classification for identifying classes of process faults. Rojas and Nandi [55] applied the

Support Vector Method for fault classification of rolling element bearings. The classification procedure was fast and effective (95% successful). A data mining based system called RMINE was developed to deal with the incomplete and noisy data in condition based monitoring of a centrifugal pump system . The major advantage of this system is its self learning ability to cope with the changing condition based data [56]. Wang *et al.* [57] proposed a data mining based approach for automatic defect detection and classification (ADD/C). They used hierarchical clustering with K means partitioning approach followed by Gaussian EM algorithm to classify the defects patterns. A fractal dimension based classifier is proposed by [58] for detection of unnatural patterns in process data.

Kusiak [59,60] applied data mining to support decision making processes by using different data-mining algorithms to generate rules for a manufacturing system. A subset of these rules was then selected to produce a control signature of the manufacturing process. The control signature is a set of feature values or ranges that lead towards an expected output. These control signatures are updated using a learning classifier based framework. Busse *et al.* [61] compared two data mining approaches for the classification of imbalanced data. In the context of a flexible manufacturing system, Horng and Lin [62] developed a hybrid classification tree (HCT) to classify the products of complicated machines. Separation matrix and fuzzy rules are used to split the data set into terminal clusters and further classification and regression tree (CART) is used for classification of terminal clusters. 40 % reduction in training time has been achieved by this method. Hsu and Wang [63] used a decision tree based approach to identify and classify significant patterns in the body shape of soldier. This sizing system provided the garment manufacturers with size specifications, design development, pattern grading and market analysis.

Liao *et al.* [64] discussed a multi-layer perceptron neural network to model radiographic welding data. Kwak and Yin [65] presented a data-mining based production-control system for testing and rework in dynamic CIM. Their system analyses the present situation and suggests dispatching rules to be followed and also how data mining can be used to evaluate the effect of those decisions. It uses decision tree based module to generate classification rules on the partitioned data that are suitable for interpretation and verification by users and stores the rule in the competitive decision selector (CDS) knowledge bases. Zhang and Jiao [66] proposed an associative classification based recommendation system for personalization in B2C e-Commerce application to anticipate customers' heterogeneous requirement. They also discussed its implementation, design and system analysis on a web based environment.

From this review, the major application areas where data mining tools and techniques are used for classification include fault diagnosis, quality control and condition monitoring. In order to perform the classification task, decision tree, rough set theory, hybrid neural network and other hybrid approaches have been successfully used. Fuzzy logic is used with these techniques to deal with noise and uncertainty in the data. However, a few works have been carried out where other functionalities are also performed with classification. Next section will deal with clustering and its performance on manufacturing databases.

5. CLUSTERING IN MANUFACTURING

Clustering is an important data mining function performed on specified manufacturing data. For example, in logistics and supply chain, order picking is routine in distribution centre. Before, picking a large set of orders, orders are clustered into batches to accelerate the product movement within the storage zone. Another example is the formation of cell in cellular manufacturing where clustering is used for design of the part families and machine cells simultaneously.

Clustering is also known as unsupervised learning. Unlike classification (supervised learning), in clustering the class object of each data object is not known. Clustering maps a data item into one of several clusters, where clusters are natural grouping of data items based on similarity metrics or probability density models [6, 67]. Within the same cluster data objects are similar to one other and are dissimilar to the objects in other clusters. Generally clustering techniques are classified in to following categories as: partitioning methods, hierarchical methods, density based methods, grid based methods, and model based methods. Liao and Wen [68] reviewed the application of artificial neural network for clustering and classification. A detailed review and study of clustering techniques, application areas are mentioned in [67].

A combination of self organizing map (SOM) neural networks and rule induction was used by [69] to identify the critical poor yield factors from normally collected wafer manufacturing data and thus increase the yield. The system is implemented with CorDex, which creates two dimensional relational topology, called “cluster map” that maintains the dimensional data interrelationship. To increase the yield of semiconductor manufacturing, Chien *et al.* [70] developed a framework consisting of Kruskal-wallis test, K-means clustering, and variance reduction splitting criteria. Sebzalli and Wang [71] applied principal component analysis and fuzzy c-means clustering to a refinery catalytic process to identify

operational spaces and develop operational strategies for the manufacture of desired products and to minimize the loss of product during system changeover. Four operational zones were discovered, with three for product grade and the fourth region giving high probability of producing off-specification product. Liao *et al.* [72] presented fuzzy clustering based techniques for the detection of welding flaws. A comparative study between fuzzy *k*-nearest neighbours clustering and fuzzy c-means clustering has been performed.

Engineering design is knowledge intensive. Jin and Ishino [73] proposed a Design Activity Knowledge Acquisition(DAKA) Framework to discover useful design activity knowledge from the CAD event data. The discovered knowledge reflects a trajectory of designers approach to reach a final design product model and identifies key design operation for specific design tasks. Kim and Ding [74] proposed a data mining aided optimal design method for fixture layout in a four station SUV side panel assembly process. Clustering and classifications are carried out for generating design library and design selection rules respectively. A comparative study of fuzzy c means clustering and crisp methods has been carried out on cell design problems. Torkul *et al.* [75] showed the outperformance of Fuzzy c means clustering over crisp methods on a selected data set. Romanowski and Nagi [76] proposed a design system which supports the feedback of data mined knowledge from the life cycle data to the initial stages of the design process. Romanowski and Nagi [77-78] applied a data-mining approach for forming generic bills of materials (GBOMS), entities that represent the different variants in a product family and facilitate the search for similar designs and the configurations of new variants. By combining data-mining approaches such as text and tree mining in a new tree union procedure that embodies the GBOM and design constraints in constrained XML, the technical difficulties associated with a GBOM are resolved. In these works, BOM are clustered into product families and subfamilies.

With the increase of automated data generation and gathering in manufacturing, mining interesting patterns is of utmost concern. Kusiak [79-80] presented various algorithms and models for data analysis including cluster analysis, precedence analysis and other data mining methods. Lee *et al.* [81] proposed an intelligent in-line measurement sampling method for process excursion monitoring and control in semiconductor manufacturing. Chip locations were clustered within the wafer through SOM classifications. It has been shown that the generated sampling method can be very effective for all defect detection despite small sampling size. Crespo and Weber [82] presented a fuzzy c means clustering based methodology for dynamic data mining and applied it on real life data. In the era of web

based design and manufacturing, web mining is now frequently used to mine useful information.

Caramia and Felici [83] applied a clique based approach to mine relevant information on web. It is used to enhance the capability of a search engine, for example to identify structural information in a set of pages, or to provide semantic extension to search for key words. Liao *et al.* [84] proposed an adaptive genetic clustering method for exploratory mining of feature vector and time series data. The proposed approach produced comparable or better clustering accuracies than k-means approach tested on bench mark datasets. Inada and Terano [85] presented a useful and effective method “QC Chart Mining” to extract the systematic patterns from quality control charts in order to manage the clinical test data. Huang *et al.* [86] presented an integrated diagnostic support system which uses hybrid rough set theory and genetic algorithm. The proposed approach has been applied at a mother board manufacturing company to discover decision rules for EMI faults. The average diagnostic accuracy of 80% showed that this hybrid model is promising for an EMI diagnostic support system.

Customer service support is an integral part of big manufacturing companies that manufacture and market expensive machines and electronic equipment. Hui and Jha [87] investigated the application of data mining techniques to extract knowledge from the customer service database for decision support and fault diagnosis. Both structured and unstructured data are mined over the world wide web. Proposed data mining technique integrates the neural network, case based reasoning, rule based reasoning for classification and clustering purposes. Symeonidis *et al.* [88] applied data mining to make the ERP system more versatile and adaptive by integrating the knowledge extracted in companies’ selling policies and thus determine the customer trend. Qian *et al.* [89] applied clustering algorithms for churn detection via customer profile modelling. Chen *et al.* [90] proposed an association rule mining based algorithm, which automatically consolidates orders into batches for minimizing the cost in terms of distance and time. In another work [91], they used association rule mining and 0-1 integer programming model for the same objective.

From this review, the major areas where clustering is used for deriving useful knowledge include customer service support, yield improvement, Fault diagnostics etc.,. The major tools and techniques used for clustering purposes include Neural Network, Fuzzy with K means or C Means clustering. However, several hybrid tools with fuzzy techniques have also been

developed for the problem specific domains. The next section will deal with prediction in manufacturing.

6. PREDICTION IN MANUFACTURING

Predictability of manufacturing process, quality, maintenance, defects, or even system is of vital importance [92]. For example in the context of maintenance, prediction can be made about what condition maintenance will be required or how equipment will deteriorate based on the analysis of past data.

Prediction is a learning function that maps a data item to a real valued prediction variable. Prediction can be viewed as the construction and use of a model to assess the class of an unlabelled sample, or to assess the value or value range of an attribute that a given sample is likely to have. Customer relations management is an area where data mining is extensively used for predicting the behaviours of customers. Morita *et al.* [93] developed a data mining server program that uses rule induction and memory based reasoning to effectively predict the customer behaviour in telecommunication industry. Tseng et al. [94] presents a data mining based hybrid approach consisting of new rough set algorithm for feature selection and multi-class Support Vector Machine (SVM) method for more accurate prediction. This technique has been applied on a case study of supplier selection problem in predicting the preferred supplier of a video game system.

Sylvain et al.[95] used different data mining techniques including decision trees, rough sets, regression and neural networks to predict component failure based on the data collected from the sensors of an aircraft. Their results also led to the design of preventive maintenance policies before the failure of any component. Lin and Tseng [96] introduced a cerebellar model articulation controller (CMAC) neural network based machine performance estimation model. CMAC-PEM was used to fuse sensory data, to predict machine reliabilities, and for condition based predictive maintenance. Yarn et al. [97] presented an intelligent predictive decision support system(IPDSS) for condition based maintenance. The proposed IPDSS model uses the recurrent neural network model in predicting the faults of critical equipment in a power plant. Earlier indication of failure provides more time for proper maintenance planning and scheduling. Zhou *et al.* [98] developed an agent based framework for intelligent prediction and monitoring of equipment failure and thereby support equipment prognostics and diagnostics. Data mining was used for the intelligent prediction engine, which is the key component of the system. Kusiak and Shah [99] proposed a data mining based robust alarm

system architecture for predicting incoming faults of water chemistry faults. The decision tree (DT) algorithm is used for learning and prediction purpose. However, the modular architecture of the developed system allows alternative knowledge generation modules to be incorporated using other data mining approaches such as simulation, analytical models and domain knowledge. Tsai *et al* [100] presented a case based reasoning (CBR) system using intelligent indexing and reasoning approaches for PCB defect prediction.

Lead time and due date estimation are important issues as they critically affect customer relations and shop floor management practices. Regression tree based DM approach has been used by Ozturk *et al.* [101], to estimate manufacturing lead time. Sha and Liu [102] incorporated a data mining tool with a due date assignment method called Total work content. The decision tree is used for mining the knowledge of job scheduling about due date assignment in a dynamic job shop environment, which is represented by IF-THEN rules. Song *et al.* [103] applied a rough set theory based approach to predict the feasibility of a plan in a complex remanufacturing system. It includes selecting training dataset, attribute discrimination, attribute reduction, rule generalization and decision making. This research provided the basis for developing a data mining based simulation method with complicated constraints. A hybrid knowledge discovery model using decision tree and back propagation neural network has been developed by [104], to determine the appropriate dispatching rule based on production data with noise information and predicting rule's performance. Chang *et al.* [105] developed an evolving fuzzy rule (EFR) method based on Wang and Mendels [106] method for due date assignment problem in manufacturing. The performance as compared with CBR and Multi-layer perceptron shows the efficacy of the approach. Chien *et al.* [107] developed a methodology for predicting cycle time based on data mining and domain knowledge, given production status and including WIP and throughput.

Model selection and cross-validation (CV) are critical issues in data collection and data mining for predicting the performance of manufacturing processes. Feng *et al* [108-109] showed that there is no significant statistical advantage of using fivefold CV over threefold CV and or of using two hidden layer neural network over one hidden layer neural nets for turning surface roughness data. Pasek [51] used the rough set theory based classifier for the prediction of cutting tool wear. For tool condition monitoring, [110] applied NN for recognition of tool condition monitoring system. Then, the support vector machine approach with two regularization parameter was employed to adjust the recognition ability for each tool wear condition separately. The experimental result showed that the proposed model can

reliably identify tool flank wear and reduce the over due prediction of worn tool conditions and its relative loss. Tseng *et al.* [111-112] proposed RST based approach to solve the quality assurance problem in predicting the acceptance of CNC machined parts, rather than focussing on the prediction of precise surface roughness values. The rule composition algorithm and rule validation procedure provides a higher accuracy prediction tool for investigating features. In context of E-Manufacturing environment, [13] applied data mining and type II fuzzy system for predicting the system output of a CNC turning operation. Feng and Wang [114] investigated the application of two competing data mining technique, regression analysis and artificial neural network, to develop the predictive model of knurling process. Fractional factorial design and design of experiment were used to plan the experiment and hypothesis testing was conducted to test the each model. It has been concluded that neural network is preferred in comparison to regression modelling.

Kusiak[115-119] extensively used data mining for medical and engineering applications. He introduced a novel data transformation method called feature bundling to improve the classification accuracy of decision rules [116]. A list of decomposition methods have been described in [117] to enhance the quality of knowledge mined from vast industrial databases. A data mining based approach was applied for identifying in-variant objects(a set of feature/parameter values) in semiconductor applications [118]. Rough set theory has been proved to be a powerful tool for discovering new knowledge and autonomous decision making. Kusiak [119] discussed the basic concept of RST as a prediction model. All these concepts follow the evolutionary computational approach for extending the longevity of knowledge. For the case where data are highly noisy, Last and Kandel [20] presented a novel perception based method called Automated Perception Network (APN), for automated construction of compact and interpretable models. Their proposed method was applied on real world dataset from semiconductor industry demonstrating the improved prediction capability of the constructed model. Li et al. [121] presented a genetic programming based DM approach for a yield prediction system and performed automated discovery of the significant factors that might cause low yield. The robustness and effectiveness of approach has been shown on well known DRAM fab's real data. An integrated yield management system, called the Advanced Statistical Bin Limit (A-SBL) system has been proposed by Kang et al. [122]. It uses inductive decision trees and neural network to manage yields over major manufacturing processes and provides functions to identify causal relationships between them such as yield prediction, process capability monitoring, feature selection, and wafer map stability monitoring. Zhou *et al.*[123] applied C4.5 algorithm for drop test

analysis of electronic goods. They focussed on predicting the integrity of the solder joints or large components on the PCBs but the approach can also be extended to other parts. A comparative study of implicit and explicit methods to predict the non-linear behaviour of the manufacturing process, using statistical procedure, neural network and case based reasoning(CBR) was discussed by Kim and Lee [124].

Knowledge elicitation is a technique that is generally used for producing rules based on human expertise. A method was developed by [125] to fuse knowledge elicitation and data mining using an expert system. Hsieh [126] developed neural network and statistical method based thermal profile model for stress level prediction under voltage stress. The ANN performance was found better in comparison to regression analysis. A novel research has been done by Mere *et al.* [127] in developing the predictive model for optimal mechanical properties of galvanised steel by using a combination of clustering and neural networks. Clustering was used in the first instance and then neural networks were applied to the clusters to predict the mechanical properties of the steel. Another interesting work is reported by Yuan *et al.* [128] in determining the toxicity (Microtox) in the process effluents from a chemical plant using neural networks and principal component analysis. Their software analyser predicts the toxicity level and helps in developing strategies in process operations for toxicity reduction in the effluents. A supervised learner for eradicating the difficulties encountered in MEWMA has been developed by Li *et al.* [129]. They show that the tree based supervised learner can potentially detect change points in the control chart as it produces predictions that are piecewise constant. A data mining approach for analyzing significance of nonlinearity effects in a multi station process has been applied by [130]. Regression tree based predictive model was used in identifying the critical factors, and responses. They also provided the guideline for users to decide when a nonlinear model should be used instead of a linear model.

Rajgopal and Castillo [131] proposed a Bayesian method that is able to set tolerance limit on one or more responses to provide a given desired probability of conformance, and to determine at the same time the optimal setting of the control factors that the responses depend upon. Past data can be used for the prediction of cycle time for a product in a factory. A comparative study of regression tree, K-nearest neighbourhood and clustering has been presented by Backus *et al.* [132] to predict the intermediate cycle time of products. Giess *et al.* [133-134] developed a predictive model for manufacturing and an assembly database of gas turbine rotors to determine and quantify relationships between the various

balance and vibration tests and highlight critical areas. This knowledge could then be fed back to the designers to improve tolerance decisions in the future design of components. They used a decision tree at the initial stage to determine appropriate areas of investigation and to identify problems with the data. At the next stage, a neural network was used to model the data. Ho et al. [135] proposed an intelligent production workflow mining system with integrated OLAP and data mining technology, combining ANN and fuzzy rule sets to realize knowledge discovery and decision support in high quality manufacturing. The result showed that their model is capable of producing accurate predictions over different manufacturing processes within production workflow. A knowledge based approximate life cycle assessment system (KALCS) is developed by Park and Seo [136], to assess the environmental impacts of product design alternatives.

From this review, major areas where prediction has been applied as data mining function include maintenance, defect prediction, manufacturing system, surface roughness, manufacturing processes and as decision support system. The data mining tools used include regression tree, ANN, rough set theory, decision induction trees and hybrid algorithms. Next section will deal with the application of association in manufacturing.

7. ASSOCIATION IN MANUFACTURING

Association rules mining were first introduced in 1993[137] and are used to identify relationships between a set of items in a database. These relationships are not based on inherent properties of the data themselves (as with functional dependencies), but rather are based on co-occurrence of the data items. Generally it is used by management for market basket type analysis to discover association rules to increase the effectiveness (and reduce the cost) associated with advertising, marketing, inventory, and stock location on the floor. In manufacturing, Association rules can be used for prediction of failure in telecommunications networks by identifying what events occur before a failure.

In design contexts, the associations between requirements may provide additional information useful for the design. For example, technical specifications might state that a car that has two doors and a diesel engine requires a specific speed transmission. In such cases, knowing the number of cars with two doors and the number of cars with a diesel engine is not relevant. To determine the capacity of manufacturing process, it is necessary to know the number of cars with two doors and a diesel engine. The nature of these association can be extracted by applying data mining algorithms on the database. More over, these associations

may have prespecified strength and confidence. A detailed survey of association rule has been carried out by [138-139].

Kusiak [60] applied rough set theory to derive associations between the process control parameters and the product families in the form of decision rules. Using the example of metal forming industry, he showed that a control signature can be found to produce good quality products. Agard and Kusiak [140] applied association rule mining base algorithm to generate the knowledge for the selection of subassemblies based on the analysis of prior orders received from the customers. The generated knowledge can be applied to construct a model for selection of subassemblies for timely delivery from the suppliers to the contractors.

Buddhakulsomsimri *et al.* [141] developed a new association rule generation algorithm to extract the knowledge (in the form of rule) used to identify the root cause of the particular warranty problem and to develop useful conclusions from automotive warranty data. This knowledge was presented in the form of IF-THEN association rules, where if portions of the rule contain the product feature attributes and the THEN portion include problem related labour code. Chen and Wu [91] applied the association rule mining to derive the association rule, which imply the customer demand pattern directly from the order databases. By applying the association function, to an order database certain sets of customer orders that frequently consists of certain product items can be inducted.

Companies design and manufacture widely diversified products to satisfy the needs of their customer and markets. Using data from aerospace industry, Shahbaz *et al.* [142] applied the association rule mining on historical product (Fan blade) data to extract the information about the process limitations and knowledge of the association between particular product dimensions. Generated information can then be feedback to establish design change requirement and product quality improvement. Agard and Kusiak [143] applied data mining to customer response data for its utilization in the design of product families. They used clustering for customer segmentation, i.e. to group the customers. The requirements from the product were then analyzed using association rules for the design of the product. Cunha *et al.* [144] applied the association rule mining for improving the quality of assembly operations. The computational result showed that the source of assembly fault can be detected using association rule, even in the presence of noise. The associations extracted can be used to improve production quality by avoiding “risky” sequences. Chao *et al.* [145] presented an intelligent system to generate associative data for input in layout generation tools. They used

an expert system, object oriented database and cluster analysis, which ensures data consistency and determines the strength of relationship between the two items under consideration. Woon *et al.* [146] proposed a method termed as Product development miner (PDMiner) to mine the web logs efficiently and effectively using association rule and sequential pattern mining. Tsai and Chang [147] proposed an intelligent design retrieval system that applies feature relation association and object form association. A Fuzzy ART neural network has been used to search for relevant designs based on object form associations.

Chen [148] used association rules for cell-formation problems. Associations among the machines are found from the process database, which leads to the identification of the occurrences of other machines with the occurrence of a machine in the cell. This approach also clusters the parts and machines into families and cells simultaneously and hence requires minimal manual judgement. Wang *et al.* [149] proposed the integration of variable precision rough set and fuzzy clustering to generate the effective association rule for manufacturing process planning. Algorithm showed the superiority over fuzzy decision technique and entropy based analysis method. Chen *et al.* [150] generated association rules for defect detection in semiconductor manufacturing. They determined the association between different machines and their combination with defects to determine the defective machine.

Jiao and Zhang [151] developed explicit decision support to improve the product portfolio identification issue by using association rule mining from past sales and product records. It discovers associations among customers needs, marketing folk and designers. In a further extension of their work, they applied an association rule mining technique to deal with product and process variety mapping [152]. The mapping relationships are embodied in association rules, which can be deployed to support production planning of product families within existing production processes. A case study of mass customization of vibration motors has been illustrated to demonstrate how the association rule mining mechanism helps maintain the coherence between product and process variety. Shao *et al.* [153] proposed a data mining based architecture to discover customer group based configuration rules in configuration design. The association rule mining based on apriori algorithm was used to get the association rules between of clusters of products specifications and configuration alternatives.

This review shows that the major area where association as a data mining function has been applied include product design, process control, mass customization, cellular design etc. Association rule mining has been applied as a dominating tool to identify the associations among variables.

8. Detailed Analysis and Discussion: A Text Mining perspective on reviewed literature

The reviewed literature shows that there is a rapid growth in the application of data mining in manufacturing, particularly in the semiconductor industry. However, there is still slow adoption of this technology in some manufacturing industries, for several reasons including:

- In any particular knowledge area, it is very difficult to determine, what type of data mining function should be performed?
- In many cases a number of data mining techniques are possible, but which technique should be used, or which one is most appropriate?

To address these questions, a novel text mining based approach has been applied on the reviewed literature's keywords and abstracts to identify patterns in the applications areas, techniques and data mining functions.

8.1 Benefits of applying Text Mining on Keyword and abstracts of reviewed literature

The objectives of this text mining are as follows:

- to automate the process of finding a research gap among the reviewed literature
- to identify any overlooked and under examined areas.
- to extract common patterns of good practices for data mining applications in manufacturing.
- to find a linkage between knowledge area, data mining function, and data mining technique used.
- to find key features which are novel for data mining users in manufacturing.

The next section discusses the text mining experiments undertaken using the abstract and keywords of 150 reviewed papers.

8.2 Knowledge Discovery in Text and Text Mining Applications on Literature Review

Following the definition of KDD by Fayyad et al. [12], Karanikous and Theoudoulidis [154] defined KDT as “the nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in unstructured data”. Text Mining (TM) is also a step in the KDT process consisting of particular data mining and natural language processing

algorithms that under certain computational efficiency and limitations produces a particular enumeration of patterns over a set of unstructured textual data. KDT in reviewed literature mainly consists of three steps as follows:

1. **Abstract and keyword collection:** In our experiments, the abstracts and key words of the literature reviewed in this paper have been collected. Key words have also been identified from the papers and added to the abstract for text mining.
2. **Retrieving and pre-processing documents:** Abstracts have only been taken from papers which deploy data mining methodology to solve problems of manufacturing. The additional key words have been identified based on knowledge area, function performed and technique used. The major knowledge areas examined include manufacturing system, quality control, fault diagnosis, maintenance, job shop, yield improvement, manufacturing process, fault diagnosis, product design, production control, and supply chain management. Similarly, the functions considered include concept description, classification, clustering, prediction and association. Major techniques used include rough set theory, decision tree, statistics, neural network, association rule, fuzzy c means clustering, regression analysis and hybrid algorithms. In this context, the term “hybrid algorithm” indicates that either a group of algorithms have been used in combination to solve a particular problem, or a group of algorithms have been used at different stages of data mining.
3. **Text Mining:** For the current purpose, text analysis and link analysis were used to extract patterns, trends, useful knowledge and meet the listed benefits.

[1] Automated process and identification of the research gaps: Our experiments tried to show if text mining could automate the process of searching for relevant literature in particular topic area and subsequently identify research gaps. Figure 2 schematically represents the extracted keywords in the form of rules. These show that very little work has been carried out in the area of supply chain management and logistics with only 5 identified examples found within the 150 papers. Barcode and Radio frequency identification (RFID) are currently the key to supply chain infrastructure. Since these techniques generates a huge amount of data they potentially provide sources of useful data for data mining based decision support systems to provide intelligent decisions. However no examples of these tools being used in data mining context were found hence, the text mining has identified a potential research gap. In addition, data mining could be used as an integral part of supply chain planning and optimization software to analyze data and transaction to give managers a range of decision choices. Other areas with low application rates of data mining and potential research gaps identified are integration of

data mining system with ERP system, production planning and control. In the area of distributed manufacturing, data mining can be integrated with agent technology which can be realized for a productive data mining system.

<<Include figure 2 about here>>

[2] Identifying the overlooked and under examined areas : Figure 2 shows the number of papers published in various areas of manufacturing. It shows that several work has been carried out in the area of data mining applications in quality control, manufacturing process, product design, fault diagnosis, maintenance, manufacturing system, job shop type problems, and yield improvement of semiconductor industries. The reasons for this may be that large volumes of data are generated during manufacture and easily available for use. Another important aspect is that most of the work has been carried out in semiconductor industries where small improvements can have a significant impact in this industry. The figure also clearly shows areas where little research has been carried out including Supply chain management, production planning and distributed manufacturing (agent technology). This may mainly be due to problems encountered during integration issues of the existing system with data mining system. Less work has been carried in the application of association rule mining in manufacturing in comparison to other approaches.

[3] Extracting common patterns of good practices: The TM experiments also showed that techniques like neural network, regression analysis, rough set theory and decision tree are mostly used for prediction purposes in manufacturing. For clustering purposes, mostly hybrid algorithms and fuzzy C means clustering has been used. Most of the hybrid algorithms include neural network as a primary tool. Similarly for the classification purposes hybrids of neural network, or rough set theory have been used. However, association rule mining has also proved to be an effective tool for identifying the association in manufacturing. These results are represented in the link analysis as shown in figure 4. This pictorially shows the linkage between found patterns, where the bolder lines show greater support in the links.

<<Include figure 3 about here>>

[4] Finding a linkage between manufacturing knowledge area, data mining function, and data mining technique used: One of the major benefits of the application of text mining on reviewed literature is to establish a linkage between, various knowledge area, data mining techniques and functions performed using link term analysis tool of text mining. It visually represents the relations between key words in the textual abstract.

Results of the link terms analysis are presented as a graph displaying a cluster of linked objects supporting various object manipulation and drill down operations. This mechanism provides the quickest way to understand the most prominent semantic characteristics of the explored data. Figure 4 shows the linkages between various manufacturing area and data mining techniques used to solve the problem. Again, the bolder lines show stronger links (or greater use).

<<Include figure 4 about here>>

It can be seen from figure 4 that some of the techniques have been more frequently used in a particular type of manufacturing area. For example, neural network is mostly applied to analyse the manufacturing process related data than others. Similarly, association rule mining has been applied more frequently to analyse product design related data.

<<Include figure 5 about here>>

Figure 5 shows the linkages between various manufacturing area and data mining functions performed. It is evident from the figure that certain type of function are more frequently applied on a particular manufacturing area. It includes, prediction in manufacturing processes, maintenance and job shop, association in product design, concept description for job shop type problem, classification in quality control. Figure 6 represents the linkages between manufacturing area, function and techniques used. It can be used to prioritize the data mining functions and technique for a particular manufacturing area. For example, It can be seen in figure 6 that there is deeper link between manufacturing process, prediction and neural network. Therefore, neural network can be used as a tool among loads of tools for prediction purposes in manufacturing process. Similarly, for association among product design related problem, priority should be given to association rule mining.

<<Include figure 6 about here>>

[5] Finding novel features for data mining users in manufacturing: The text mining experiments also enabled some of the novel features which were commonly used by data mining practitioners in manufacturing to be identified. One of them is the increased use of hybrid algorithms in manufacturing. There is universally best data mining methods for all manufacturing contexts. Therefore, there is an increased used of combinations of traditional data mining algorithms to capture advantages from each technique used. It has been found that in order to perform several functions in a problem area several algorithms may be used at different stages of data mining. Another noticeable factor is the use of Fuzzy sets with various data mining techniques. One of the reason for this may be, that fuzzy sets are inherently inclined towards coping with linguistic domain knowledge and producing more interpretable solutions. In addition, fuzzy sets in association with a particular data mining technology are capable of handling the issues related to understadability of patterns,

incomplete and noisy data, and human interaction, and can provide approximate solutions faster. It has been found that hybridization of neural network and fuzzy logic is of increased use in manufacturing. In addition, researchers and practitioners have also modelled, or advanced the existing algorithms according to the problem environment. Thus, it can be said that hybridization of data mining algorithms may lead to a better solution quality comparison to existing and traditional algorithms.

9. CONCLUSION

Knowledge discovery and data mining have created new intelligent tools for extracting useful information and knowledge automatically from manufacturing databases. The present article provides a survey of the available literature on data mining applications in manufacturing with a special emphasis on the kind of knowledge mined. Type of knowledge indicates the major data mining functions to be performed include characterization and description, association, classification, prediction, clustering in data. It has been found that there is an exponential growth in the number of papers in last 3 years.

A novel text mining approach has been applied on the reviewed literature to identify the research gap, examine the under looked and overlooked areas, identifying good practices data mining in manufacturing and some key features unknown to data mining practitioners. A correlation and linkage has been established between knowledge area, knowledge mined and technique used based on the past practices to provide the user a choice of technique. It has been found that some area such as supply chain management, production planning and control, and integration of data mining system with existing system needs attention for the research community.
