Contribution of fibrinolysis to the physical component summary of the SF-36 after acute submassive pulmonary embolism

Stewart L.K., Peitz G.W., Nordenholz K.E., Courtney D.M., Kabrhel C., Jones A.E., Rondina M.T., Diercks D.B., Klinger J.R., Kline J.A.

Journal of Thrombosis and Thrombolysis 2015 40:2 (161-166)

Acute pulmonary embolism (PE) can diminish patient quality of life (QoL). The objective was to test whether treatment with tenecteplase has an independent effect on a measurement that reflects QoL in patients with submassive PE. This was a secondary analysis of an 8-center, prospective randomized controlled trial, utilizing multivariate regression to control for predefined predictors of worsened QoL including: age, active malignancy, history of PE or deep venous thrombosis (DVT), recurrent PE or DVT, chronic obstructive pulmonary disease and heart failure. QoL was measured with the physical component summary (PCS) of the SF-36. Analysis included 76 patients (37 randomized to tenecteplase, 39 to placebo). Multivariate regression yielded an equation f(8, 67), P < 0.001, with R² = 0.303. Obesity had the largest effect on PCS (β = -8.6, P < 0.001), with tenecteplase second (β = 4.73, P = 0.056). After controlling for all interactions, tenecteplase increased the PCS by +5.37 points (P = 0.027). In patients without any of the defined comorbidities, the coefficient on the tenecteplase variable was not significant (-0.835, P = 0.777). In patients with submassive PE, obesity had the greatest influence on QoL, followed by use of fibrinolysis. Fibrinolysis had a marginal independent effect on patient QoL after controlling for comorbidities, but was not significant in patients without comorbid

Retinoid receptor signaling and autophagy in acute promyelocytic leukemia

Orfali N., McKenna S.L., Cahill M.R., Gudas L.J., Mongan N.P. Experimental Cell Research 2014 **324:1** (1-12)

Retinoids are a family of signaling molecules derived from vitamin A with well established roles in cellular differentiation. Physiologically active retinoids mediate transcriptional effects on cells through interactions with retinoic acid (RARs) and retinoid-X (RXR) receptors. Chromosomal translocations involving the RARa gene, which lead to impaired retinoid signaling, are implicated in acute promyelocytic leukemia (APL). All-trans-retinoic acid (ATRA), alone and in combination with arsenic trioxide (ATO), restores differentiation in APL cells and promotes degradation of the abnormal oncogenic fusion protein through several proteolytic mechanisms. RAR. a fusion-protein elimination is emerging as critical to obtaining sustained remission and long-term cure in APL. Autophagy is a degradative cellular pathway involved in protein turnover. Both ATRA and ATO also induce autophagy in APL cells. Enhancing autophagy may therefore be of therapeutic benefit in resistant APL and could broaden the application of differentiation therapy to other cancers. Here we discuss retinoid signaling in hematopoiesis, leukemogenesis, and APL treatment. We highlight autophagy as a potential important regulator in anti-leukemic strategies. © 2014 Elsevier Inc.

Heme oxygenase-1 and acute kidney injury following cardiac surgery

Billings F.T., Yu C., Byrne J.G., Petracek M.R., Pretorius M.

CardioRenal Medicine 2014 4:1 (12-21)

Background: Intraoperative hemolysis and inflammation are associated with acute kidney injury (AKI) following cardiac surgery. Plasma-free hemoglobin induces heme oxygenase-1 (HO-1) expression. HO-1 degrades heme but increases in experimental models of AKI. This study tested the hypothesis that plasma HO-1 concentrations are associated with intraoperative hemolysis and are increased in patients that develop AKI following cardiac surgery. Methods: We measured plasma HO-1, free hemoglobin, and inflammatory markers in 74 patients undergoing cardiopulmonary bypass (CPB). AKI was defined as an increase in serum creatinine concentration of 50% or 0.3 mg/dl within 72 h of surgery. Results: Twenty-eight percent of patients developed AKI. HO-1 concentrations increased from 4.2 ± 0.2 ng/ml at baseline to 6.6 ± 0.5 ng/ml on postoperative day (POD) 1 (p < 0.001). POD1 HO-1 concentrations were 3.1 ng/ml higher (95% CI 1.1-5.1) in AKI patients, as was the change in HO-1 from baseline to POD1 (4.4 \pm 1.3 ng/ml in AKI patients vs. 1.5 \pm 0.3 ng/ml in no-AKI patients, p = 0.006). HO-1 concentrations remained elevated in AKI patients even after controlling for AKI risk factors and preoperative drug therapy. Peak-free hemoglobin concentrations correlated with peak HO-1 concentrations on POD1 in patients that developed AKI (p = 0.02). Duration of CPB and post-CPB IL-6 and IL-10 concentrations were also associated with increased HO-1 on POD1. Conclusion: Plasma HO-1 is increased in patients that develop AKI, and CPB duration, hemolysis, and inflammation are associated with increased HO-1 concentrations following cardiac surgery. Strategies that alter hemolysis and HO-1 expression during cardiac surgery may affect risk for AKI. © 2014 S. Karger AG. Basel.

Intraventricular Tissue Plasminogen Activator in Subarachnoid Hemorrhage Patients: A Prospective, Randomized, Placebo-Controlled Pilot Trial

Kramer A.H., Roberts D.J., Holodinsky J., Todd S., Hill M.D., Zygun D.A., Faris P., Wong J.H.

Neurocritical Care 2014 21:2 (275-284)

Background: The quantity of subarachnoid (SAH) and intraventricular hemorrhage (IVH) occurring in the setting of a ruptured cerebral aneurysm is strongly associated with subsequent complications and poor outcomes. Methods: We randomly allocated aneurysmal SAH patients with a modified Fisher score of 4, who had been treated with endovascular coil embolization and ventricular drainage, to receive either 2 mg intraventricular tissue plasminogen activator (TPA) every 12 h (maximum 10 mg) or placebo. Computed tomography scans were performed 12, 48, and 72 h after administration. Primary outcomes included feasibility (enrollment and consent rates), safety (assessed by prospectively screening for complications), and rate of intracranial blood clearance (measured using sequential IVH, modified Graeb, and SAH sum scores). Secondary outcomes included angiographic vasospasm, delayed cerebral ischemia, need for ventriculoperitoneal shunting, and 6-month neurological outcomes. Results: Seventyseven patients were screened, 17 were eligible, and 12 were randomized. The consent rate was 87 %. There were no cases of new intracranial hemorrhage complicating use of TPA. Models fit using generalized estimating equations demonstrated more rapid reduction in IVH volume (p = 0.009), modified Graeb score (p < 0.001), and SAH sum score (p < 0.001) among patients treated with TPA. SAH clearance at 48 h was enhanced by earlier drug administration (p = 0.02). There were no differences in secondary outcomes. Conclusions: Intraventricular TPA accelerates clearance of SAH and IVH, especially when administered early. A larger-scale clinical trial of intraventricular TPA is feasible, will need to be conducted at multiple centers, and is required to determine whether this practice reduces complications and improves outcomes. © 2014, Springer Science+Business Media New York.

Effect of almond consumption on the serum fatty acid profile: A dose-response study

Nishi S., Kendall C.W.C., Gascoyne A.-M., Bazinet R.P., Bashyam B., Lapsley K.G., Augustin L.S.A., Sievenpiper J.L., Jenkins D.J.A.

British Journal of Nutrition 2014 112:7 (1137-1146)

Consumption of almonds has been shown to be associated with a decreased risk of CHD. which may be related to their fatty acid (FA) composition. However, the effect of almond consumption on the serum FA composition is not known. Therefore, in the present study, we investigated whether almond consumption would alter the serum FA profile and risk of CHD, as calculated using Framingham's 10-year risk score, in a dosedependent manner in hyperlipidaemic individuals when compared with a highercarbohydrate control group using dietary interventions incorporating almonds. A total of twenty-seven hyperlipidaemic individuals consumed three isoenergetic (mean 1770 kJ/d) supplements during three 1-month dietary phases: (1) full-dose almonds (50-100 g/d); (2) half-dose almonds with half-dose muffins; (3) full-dose muffins. Fasting blood samples were obtained at weeks 0 and 4 for the determination of FA concentrations. Almond intake (q/d) was found to be inversely associated with the estimated Framingham 10-year CHD risk score (P= 0.026). In both the half-dose and full-dose almond groups, the proportions of oleic acid (OA) and MUFA in the TAG fraction (halfalmond: OA P= 0.003; MUFA P= 0.004; full-almond: OA P< 0.001; MUFA P< 0.001) and in the NEFA fraction (half-almond: OA P= 0.01; MUFA P= 0.04; full-almond: OA P= 0.12; MUFA P= 0.06) increased. The estimated Framingham 10-year CHD risk score was inversely associated with the percentage change of OA (P= 0.011) and MUFA (P= 0.016) content in the TAG fraction. The proportions of MUFA in the TAG and NEFA fractions were positively associated with changes in HDL-cholesterol concentrations. Similarly, the estimated Framingham 10-year CHD risk score was inversely associated with the percentage change of OA (P = 0.069) and MUFA content in the NEFA fraction (P = 0.069) 0.009). In conclusion, the results of the present study indicate that almond consumption increases OA and MUFA content in serum TAG and NEFA fractions, which are inversely associated with CHD lipid risk factors and overall estimated 10-year CHD risk. © The Authors 2014.

Treatment of submassive pulmonary embolism with tenecteplase or placebo: Cardiopulmonary outcomes at 3 months: Multicenter double-blind, placebo-controlled randomized trial

Kline J.A., Nordenholz K.E., Courtney D.M., Kabrhel C., Jones A.E., Rondina M.T., Diercks D.B., Klinger J.R., Hernandez J.

Journal of Thrombosis and Haemostasis 2014 12:4 (459-468)

Summary: Background: Acute pulmonary embolism (PE) can worsen quality of life due to persistent dyspnea or exercise intolerance. Objective: Test if tenecteplase increases the probability of a favorable composite patient-oriented outcome after submassive PE. Methods: Normotensive patients with PE and right ventricular (RV) strain (by echocardiography or biomarkers) were enrolled from eight hospitals. All patients received low-molecular-weight heparin followed by random assignment to either a single weight-based bolus of tenecteplase or placebo, administered in a double-blinded fashion. The primary composite outcome included: (i) death, circulatory shock, intubation or major bleeding within 5 days or (ii) recurrent PE, poor functional capacity (RV dysfunction with either dyspnea at rest or exercise intolerance) or an SF36® Physical Component Summary (PCS) score < 30 at 90-day follow-up. Results: Eighty-three patients were randomized; 40 to tenecteplase and 43 to placebo. The trial was terminated prematurely. Within 5 days, adverse outcomes occurred in three placebotreated patients (death in one and intubation in two) and one tenecteplase-treated patient (fatal intracranial hemorrhage). At 90 days, adverse outcomes occurred in 13 unique placebo-treated patients and five unique tenecteplase-treated patients Thus, 16 (37%) placebo-treated and six (15%) tenecteplase-treated patients had at least one adverse outcome (exact two-sided P = 0.017). Conclusions: Treatment of patients with submassive pulmonary embolism with tenecteplase was associated with increased probability of a favorable composite outcome. © 2014 International Society on Thrombosis and Haemostasis.

Treatment of Malignant Brain Edema and Increased Intracranial Pressure After Stroke

Brogan M.E., Manno E.M.

Current Treatment Options in Neurology 2014 17:1

The management of patients with large territory ischemic strokes and the subsequent development of malignant brain edema and increased intracranial pressure is a significant challenge in modern neurology and neurocritical care. These patients are at high risk of subsequent neurologic decline and are best cared for in an intensive care unit or a comprehensive stroke center with access to neurosurgical support. Risks include hemorrhagic conversion, herniation, poor functional outcome, and death. This review discusses recent advances in understanding the pathophysiology of edema formation, identifying patients at risk, current management strategies, and emerging therapies.

Minocycline repurposing in critical illness: Focus on stroke Liao T.V., Forehand C.C., Hess D.C., Fagan S.C.

Current Topics in Medicinal Chemistry 2013 13:18 (2283-2290)

Stroke is a devastating disease associated with high morbidity and mortality. Despite the approved indication of systemic thrombolytic therapy in the United States for the acute management of ischemic stroke, its use is limited given a strict eligibility criteria and a risk for hemorrhagic transformation as a feared adverse effect. Many agents have been studied without success for neuroprotection in patients with stroke to reduce vascular injury and improve long-term functional outcomes. Minocycline is a tetracycline antibiotic that shows promise for its neuroprotective effects in multiple animal models and three human trials. It affects multiple pathways to reduce apoptosis, neuroinflammation, infarct size, and vascular injury. The aim of this review is to discuss current evidence for minocycline from pre-clinical and early clinical trials and its potential role in neuroprotection in patients with acute ischemic stroke. © 2013 Bentham Science Publishers.

Role of inflammation and its mediators in acute ischemic stroke $\mbox{\rm Jin}\ R.,\ \mbox{\rm Liu}\ \mbox{\rm L.},\ \mbox{\rm Zhang}\ \mbox{\rm S.},\ \mbox{\rm Nanda}\ \mbox{\rm A.},\ \mbox{\rm Li}\ \mbox{\rm G.}$

Journal of Cardiovascular Translational Research 2013 6:5 (834-851) Inflammation plays an important role in the pathogenesis of ischemic stroke and other forms of ischemic brain injury. Increasing evidence suggests that inflammatory response is a double-edged sword, as it not only exacerbates secondary brain injury in the acute stage of stroke but also beneficially contributes to brain recovery after stroke. In this article, we provide an overview on the role of inflammation and its mediators in acute ischemic stroke. We discuss various pro-inflammatory and anti-inflammatory responses in different phases after ischemic stroke and the possible reasons for their failures in clinical trials. Undoubtedly, there is still much to be done in order to translate promising pre-clinical findings into clinical practice. A better understanding of the dynamic balance between pro- and anti-inflammatory responses and identifying the discrepancies between pre-clinical studies and clinical trials may serve as a basis for designing effective therapies. © 2013 Springer Science+Business Media New York.

D-penicillamine and other low molecular weight thiols: Review of anticancer effects and related mechanisms

Wadhwa S., Mumper R.J.

Cancer Letters 2013 337:1 (8-21)

Low molecular weight thiols (LMWTs) like N-acetyl cysteine, D-penicillamine, captopril, Disulfiram and Amifostine, etc. have been used as chemo-preventive agents. Recent studies have reported cell growth inhibition and cytotoxicity in several different types of cancer cells following treatment with several LMWTs. Cytotoxic and cytostatic effects of LMWTs may involve interaction of the thiol group with cellular lipids, proteins, intermediates or enzymes. Some of the mechanisms that have been proposed include a p53 mediated apoptosis, thiyl radical induced DNA damage, membrane damage through lipid peroxidation, anti-angiogenic effects induced by inhibition of matrix metalloproteinase enzymes and angiostatin generation. LMWTs are strong chelators of transition metals like copper, nickel, zinc, iron and cobalt and may cause metal co-factor depletion resulting in cytotoxicity. Oxidation of thiol group can also generate cytotoxic reactive oxygen species (ROS). © 2013 Elsevier Ireland Ltd.

RNA in blood is altered prior to hemorrhagic transformation in ischemic stroke

Jickling G.C., Ander B.P., Stamova B., Zhan X., Liu D., Rothstein L., Verro P., Khoury J., Jauch E.C., Pancioli A.M., Broderick J.P., Sharp F.R. **Annals of Neurology** 2013 **74:2** (232-240)

Objective Hemorrhagic transformation (HT) is a major complication of ischemic stroke

that worsens outcomes and increases mortality. Disruption of the blood-brain barrier is a central feature of HT pathogenesis, and leukocytes may contribute to this process. We sought to determine whether ischemic strokes that develop HT have differences in RNA expression in blood within 3 hours of stroke onset prior to treatment with thrombolytic therapy. Methods Stroke patient blood samples were obtained prior to treatment with thrombolysis, and leukocyte RNA was assessed by microarray analysis. Strokes that developed HT (n = 11) were compared to strokes without HT (n = 33) and controls (n = 11) 14). Genes were identified (corrected p < 0.05, fold change \geq |1.2|), and functional analysis was performed. RNA prediction of HT in stroke was evaluated using crossvalidation, and in a second stroke cohort (n = 52). Results Ischemic strokes that developed HT had differential expression of 29 genes in circulating leukocytes prior to treatment with thrombolytic therapy. A panel of 6 genes could predict strokes that later developed HT with 80% sensitivity and 70.2% specificity. Key pathways involved in HT of human stroke are described, including amphiregulin, a growth factor that regulates matrix metalloproteinase-9; a shift in transforming growth factor-β signaling involving SMAD4, INPP5D, and IRAK3; and a disruption of coagulation factors V and VIII. Interpretation Identified genes correspond to differences in inflammation and coagulation that may predispose to HT in ischemic stroke. Given the adverse impact of HT on stroke outcomes, further evaluation of the identified genes and pathways is warranted to determine their potential as therapeutic targets to reduce HT and as markers of HT risk. © 2013 American Neurological Association.

Thrombolytic therapy for submassive pulmonary embolism Lankeit M., Konstantinides S.

Best Practice and Research: Clinical Haematology 2012 25:3 (379-389) Approximately 10% of all patients with acute pulmonary embolism (PE) die within the first three months after diagnosis. However, PE is not universally life-threatening, but covers a wide spectrum of clinical severity and death risk. Thrombolytic treatment is indicated patients with acute massive PE who are at high risk for early death, i.e. those patients who present with arterial hypotension and shock. On the other hand, low molecular-weight heparin or fondaparinux is adequate treatment for most normotensive patients with PE. Recombinant tissue plasminogen activator, given as 100 mg infusion over 2 h, is the treatment of choice for patients with PE, although older regimens using urokinase or streptokinase are also efficacious. Beyond the relatively small numbers of patients with massive, high-risk PE as a target population for thrombolysis, there is increasing awareness of the need for risk stratification of normotensive patients and the search for an intermediate-risk group (also called submassive PE). Recent metaanalyses of cohort studies suggest that imaging of the right ventricle or biomarkers of myocardial injury alone may be insufficient for guiding therapeutic decisions. Instead, accumulating evidence appears to support strategies which combine the information provided by an imaging procedure with a biomarker test. These data provide the rationale for a large multinational randomized trial which has set out to determine whether normotensive patients with right ventricular dysfunction, detected by echocardiography or computed tomography, plus evidence of myocardial injury as indicated by a positive troponin test, may benefit from early thrombolytic treatment. This study, which is underway in 13 European countries, will enroll a total of 1000 patients and will be completed in 2012. Together with a parallel trial currently being conducted in the United States, it will hopefully answer the question whether thrombolysis is indicated in submassive PE, thus terminating a 40-year-old debate and filling an important gap in our management concept for acute pulmonary embolism. © 2012 Published by Elsevier Ltd.

Prediction of cardioembolic, arterial, and lacunar causes of cryptogenic stroke by gene expression and infarct location Jickling G.C., Stamova B., Ander B.P., Zhan X., Liu D., Sison S.-M., Verro P., Sharp F.R.

Stroke 2012 **43:8** (2036-2041)

BACKGROUND AND PURPOSE-: The cause of ischemic stroke remains unclear, or cryptogenic, in as many as 35% of patients with stroke. Not knowing the cause of stroke restricts optimal implementation of prevention therapy and limits stroke research. We demonstrate how gene expression profiles in blood can be used in conjunction with a measure of infarct location on neuroimaging to predict a probable cause in cryptogenic stroke. METHODS-: The cause of cryptogenic stroke was predicted using previously described profiles of differentially expressed genes characteristic of patients with cardioembolic, arterial, and lacunar stroke. RNA was isolated from peripheral blood of 131 cryptogenic strokes and compared with profiles derived from 149 strokes of known cause. Each sample was run on Affymetrix U133 Plus 2.0 microarrays. Cause of cryptogenic stroke was predicted using gene expression in blood and infarct location. RESULTS-: Cryptogenic strokes were predicted to be 58% cardioembolic, 18% arterial, 12% lacunar, and 12% unclear etiology. Cryptogenic stroke of predicted cardioembolic etiology had more prior myocardial infarction and higher CHA2DS2-VASc scores compared with stroke of predicted arterial etiology. Predicted lacunar strokes had higher systolic and diastolic blood pressures and lower National Institutes of Health Stroke Scale compared with predicted arterial and cardioembolic strokes. Cryptogenic strokes of unclear predicted etiology were less likely to have a prior transient ischemic attack or ischemic stroke. CONCLUSIONS-: Gene expression in conjunction with a measure of infarct location can predict a probable cause in cryptogenic strokes. Predicted groups require further evaluation to determine whether relevant clinical, imaging, or therapeutic differences exist for each group. © 2012 American Heart Association, Inc.

A double blind randomized cross over trial comparing rate of decortication and efficacy of intrapleural instillation of alteplase vs placebo in patients with empyemas and complicated parapneumonic effusions

Thommi G., Shehan J.C., Robison K.L., Christensen M., Backemeyer L.A., McLeay M.T.

Respiratory Medicine 2012 106:5 (716-723)

Aim: A double blind randomized cross over trial to compare the rate of decortication, safety and efficacy of intrapleural instillation of Alteplase vs. Placebo in empyema and complicated parapneumonic effusions (CPE). Methods: Patients diagnosed with empyema or CPE and considered for surgery were given the option to enter into this trial. Intrapleural instillation of the 'Drug' was given daily for three days. Patient that failed the first arm of the trial were offered surgery or to cross over to the second arm. Failure was documented if pleural effusions did not improve by 50% on CT scans after three doses of the 'Drug' or if these effusions recurred within six weeks. Results: One hundred and eight patients were evaluated and one hundred enrolled in the trial. 32 patients were excluded, 29 for noninfectious loculated effusions, two for protocol violation and one for bleeding at chest tube site. There were 17 patients with empyema and 51 patients with CPE. 58 of the 61 patients (26 crossed over) with empyema/CPE resolved with Alteplase therapy compared to 4 of the 32 patients (one crossed over) treated with Placebo (p value <0.001). None of the patients went to surgery. Adverse events with Alteplase therapy compared to Placebo were not statistically significant, with chest pain and bleeding complications being the most common. Conclusion: Intrapleural instillation of Alteplase is significantly more effective than Placebo in patients with empyema and PPE (95% vs.12%). This study demonstrates it is safe and efficacious with minimal adverse reactions. © 2011 Elsevier Ltd. All rights reserved.

Thrombolysis and Deferoxamine in Middle Cerebral Artery Occlusion (TANDEM-1). A randomized controlled trial

Millán M., Pérez De La Ossa N., Reverté S., Silva Y., Nombela F., Rodríguez-Yáñez M., Costa J., Giner P., Castillo J., Serena J., Vivancos J., Dávalos A.

Cerebrovascular Diseases 2012 33 SUPPL. 2 (714)

Background and Purpose: Iron overload is associated with greater brain injury whereas deferoxamine (DFO), an iron chelator, offers neuroprotection in animal models of cerebral ischemia and reperfusion. We aimed to evaluate safety and prove of concept of efficacy of IV DFO in patients with acute ischemic stroke (AIS) of middle cerebral artery territory treated with IV tissue plasminogen activator (tPA) within 3 hours from symptoms onset. Methods:TANDEM-1 was a placebo-controlled, double-blind, randomized, dose-finding phase II clinical trial (NCT00777140). A single 10mg/Kg bolus of DFO followed by a 72-hour continuous infusion escalating through 20, 40 and 60 mg/Kg/24h (n=15 per group) or placebo (n=5 per group) was initiated within the 1-hour of tPA infusion. A non blinded independent investigator evaluated serious adverse events (SAE) after each dose tier. Primary efficacy endpoint was good clinical outcome (modified Rankinscale ≤ 2) at 90 days. Results: The three parts terminated without crossing the safety stopping rules. Two patients with violation of inclusion criteria were substituted, but considered for safety analyses. Forty-seven patients received DFO and 15 placebo. Mean age and NIHSS score were 66.7 versus 64.6 years and 13.4 versus 17.2. SAE were reported in 13/47 (27.7%) and 4/15 (26.6%) patients. No SAE was related to DFO infusion except a non-fatal anaphylactic reaction. DFO was also discontinued in three patients because of asymptomatic bradicardia (n=2) and early neurological worsening (n=1). Symptomatic ICH (4.3% versus 0%) and mortality (14.9% versus 13.3%) were not different between groups. Good outcome was found in 55.6% of DFOtreated patients (53.3%, 53.3%, 60% for each tier) and in 40% of placebo group. Conclusions: Intravenous DFO initiated during the tPA infusion time is safe and well-tolerated up to doses of 60 mg/Kg/ day for three days. These findings provide the basis for a second trial aimed to demonstrate safety and efficacy of DFO.

Y chromosome gene expression in the blood of male patients with ischemic stroke compared with male controls

Tian Y., Stamova B., Jickling G.C., Xu H., Liu D., Ander B.P., Bushnell C., Zhan X., Turner R.J., Davis R.R., Verro P., Pevec W.C., Hedayati N., Dawson D.L., Khoury J., Jauch E.C., Pancioli A., Broderick J.P., Sharp F.R. Gender Medicine 2012 9:2 (68-75.e3)

Background: Sex is suggested to be an important determinant of ischemic stroke risk factors, etiology, and outcome. However, the basis for this remains unclear. The Y chromosome is unique in males. Genes expressed in males on the Y chromosome that are associated with stroke may be important genetic contributors to the unique features of males with ischemic stroke, which would be helpful for explaining sex differences observed between men and women. Objective: We compared Y chromosome gene expression in males with ischemic stroke and male controls. Methods: Blood samples were obtained from 40 male patients ≤3, 5, and 24 hours after ischemic stroke and from 41 male controls (July 2003-April 2007). RNA was isolated from blood and was processed using Affymetrix Human U133 Plus 2.0 expression arrays (Affymetrix Inc., Santa Clara, California). Y chromosome genes differentially expressed between male patients with stroke and male control subjects were identified using an ANCOVA adjusted for age and batch. A P < 0.05 and a fold change > 1.2 were considered significant. Results: Seven genes on the Y chromosome were differentially expressed in males with ischemic stroke compared with controls. Five of these genes (VAMP7, CSF2RA, SPRY3, DHRSX, and PLCXD1) are located on pseudoautosomal regions of the human Y chromosome. The other 2 genes (EIF1AY and DDX3Y) are located on the nonrecombining region of the human Y chromosome. The identified genes were associated with immunology, RNA metabolism, vesicle fusion, and angiogenesis. Conclusions: Specific genes on the Y chromosome are differentially expressed in blood after ischemic stroke. These genes provide insight into potential molecular contributors to sex differences in ischemic stroke. © 2012 Elsevier HS Journals, Inc. All rights reserved.

NF-κB and the link between inflammation and cancer

Didonato J.A., Mercurio F., Karin M.

Immunological Reviews 2012 246:1 (379-400)

The nuclear factor-κB (NF-κB) transcription factor family has been considered the central mediator of the inflammatory process and a key participant in innate and adaptive immune responses. Coincident with the molecular cloning of NF-κB/RelA and identification of its kinship to the v-Rel oncogene, it was anticipated that NF-κB itself would be involved in cancer development. Oncogenic activating mutations in NF-κB genes are rare and have been identified only in some lymphoid malignancies, while most NF-κB activating mutations in lymphoid malignancies occur in upstream signaling components that feed into NF-κB. NF-κB activation is also prevalent in carcinomas, in which NF-κB activation is mainly driven by inflammatory cytokines within the tumor microenvironment. Importantly, however, in all malignancies, NF-κB acts in a cell type-specific manner: activating survival genes within cancer cells and inflammation-promoting genes in components of the tumor microenvironment. Yet, the complex biological functions of NF-κB have made its therapeutic targeting a challenge. © 2012 John Wiley & Sons A/S.

Cardiac hypertrophy and fibrosis in the metabolic syndrome: A role for aldosterone and the mineralocorticoid receptor Essick E.E., Sam F.

International Journal of Hypertension 2011 **2011** Article Number 346985 Obesity and hypertension, major risk factors for the metabolic syndrome, render individuals susceptible to an increased risk of cardiovascular complications, such as adverse cardiac remodeling and heart failure. There has been much investigation into the role that an increase in the renin-angiotensin-aldosterone system (RAAS) plays in the pathogenesis of metabolic syndrome and in particular, how aldosterone mediates left

14/7/2015

ventricular hypertrophy and increased cardiac fibrosis via its interaction with the mineralocorticoid receptor (MR). Here, we review the pertinent findings that link obesity with elevated aldosterone and the development of cardiac hypertrophy and fibrosis associated with the metabolic syndrome. These studies illustrate a complex cross-talk between adipose tissue, the heart, and the adrenal cortex. Furthermore, we discuss findings from our laboratory that suggest that cardiac hypertrophy and fibrosis in the metabolic syndrome may involve cross-talk between aldosterone and adipokines (such as adiponectin). © 2011 Eric E. Intravitreal tissue plasminogen activator to treat refractory diabetic macular edema by induction of posterior vitreous detachment

Abrishami M., Moosavi M.N., Shoeibi N., Hosseinpoor S.S. Retina 2011 **31:10** (2065-2070)

PURPOSE:: To evaluate the effects of intravitreal injection of recombinant tissue plasminogen activator (TPA) for the treatment of refractory diabetic macular edema. METHODS:: A total of 27 patients with refractory diabetic macular edema with no evidence of posterior vitreous detachment were randomly assigned into follow-up (F/U) or TPA treatment groups. To control for the effects of intravitreal injection, an additional 14 patients with diabetic macular edema who were candidates for first-time intravitreal bevacizumab injection were enrolled as the IVB group. For the TPA and IVB groups, 25

μg of TPA or 1.25 mg of bevacizumab, respectively, were intravitreally injected. Fundoscopy, optical coherence tomography, and B-scan ultrasonography were performed at 1 week, 1 month, and 3 months after initiation of the study. RESULTS:: The incidence of posterior vitreous detachment in fundoscopy over the follow-up period was 69.2% in the TPA group, which was significantly higher than that of the F/U and IVB groups (P = 0.001). Best-corrected visual acuity and changes in macular thickness did not significantly differ between the TPA and F/U groups over the 3-month period. CONCLUSION:: Intravitreal TPA injection induces posterior vitreous detachment in patients with diabetic macular edema refractory to standard treatment but has no effect on macular thickness or best-corrected visual acuity within 3 months. © The Ophthalmic Communications Society, Inc.

Protective conditioning of the brain: Expressway or roadblock? Mergenthaler P., Dirnagl U.

Journal of Physiology 2011 589:17 (4147-4155)

The brain responds to noxious stimulation with protective signalling. Over the last decades, a number of experimental strategies have been established to study endogenous brain protection. Pre-, per-, post- and remote 'conditioning' are now widely used to unravel the underlying mechanisms of endogenous neuroprotection. Some of these strategies are currently being tested in clinical trials to protect the human brain against anticipated damage or to boost protective responses during or after injury. Here we summarize the principles of 'conditioning' research and current efforts to translate this knowledge into effective treatment of patients. Conditioning to induce protected brain states provides an experimental window into endogenous brain protection and can lead to the discovery of drugs mimicking the effects of conditioning. Mechanisms of endogenous brain tolerance can be activated through a wide variety of stimuli that

signal 'danger' to the brain. These danger signals lead to the induction of regulator and effector mechanisms, which suppress death and induce survival pathways, decrease metabolism, as well as increase substrate delivery. We conclude that preclinical research on endogenous brain protection has greatly benefited from conditioning strategies, but that clinical applications are challenging, and that we should not prematurely rush into ill-designed and underpowered clinical trials. © 2011 The Authors. Profiles of lacunar and nonlacunar stroke

Jickling G.C., Stamova B., Ander B.P., Zhan X., Tian Y., Liu D., Xu H., Johnston S.C., Verro P., Sharp F.R.

Annals of Neurology 2011 **70:3** (477-485)

Objective: Determining which small deep infarcts (SDIs) are of lacunar, arterial, or cardioembolic etiology is challenging, but important in delivering optimal stroke

prevention therapy. We sought to distinguish lacunar from nonlacunar causes of SDIs using a gene expression profile. Methods: A total of 184 ischemic strokes were analyzed. Lacunar stroke was defined as a lacunar syndrome with infarction <15mm in a region supplied by penetrating arteries. RNA from blood was processed on whole genome microarrays. Genes differentially expressed between lacunar (n = 30) and nonlacunar strokes (n = 86) were identified (false discovery rate \leq 0.05, fold changegt|1.5|) and used to develop a prediction model. The model was evaluated by cross-validation and in a second test cohort (n = 36). The etiology of SDIs of unclear cause (SDIs a; circyen 15mm or SDIs with potential embolic source) (n = 32) was predicted using the derived model. Results: A 41-gene profile discriminated lacunar from nonlacunar stroke with>90% sensitivity and specificity. Of the 32 SDIs of unclear cause, 15 were predicted to be lacunar, and 17 were predicted to be nonlacunar. The identified profile represents differences in immune response between lacunar and nonlacunar stroke. Interpretation: Profiles of differentially expressed genes can distinguish lacunar from nonlacunar stroke. SDIs of unclear cause were frequently predicted to be of nonlacunar etiology, suggesting that comprehensive workup of SDIs is important to identify potential cardioembolic and arterial causes. Further study is required to evaluate the gene profile in an independent cohort and determine the clinical and treatment implications of SDIs of predicted nonlacunar etiology. © 2011 American Neurological Association.

A phase III, open-label, single-arm study of tenecteplase for restoration of function in dysfunctional central venous catheters Tebbi C., Costanzi J., Shulman R., Dreisbach L., Jacobs B.R., Blaney M., Ashby M., Gillespie B.S., Begelman S.M.

Journal of Vascular and Interventional Radiology 2011 22:8 (1117-1123) Purpose: To evaluate, in a phase III, single-arm study, the safety and efficacy of the thrombolytic agent tenecteplase in restoring function to dysfunctional central venous catheters (CVCs). Materials and Methods: Pediatric and adult patients with dysfunctional CVCs were eligible to receive as much as 2 mL (2 mg) of intraluminal tenecteplase, which was left to dwell in the CVC lumen for a maximum of 120 minutes. If CVC function was not restored at 120 minutes, a second dose was instilled for an additional 120 minutes. Results: Tenecteplase was administered to 246 patients. Mean patient age was 44 years (range, 092 y); 72 patients (29%) were younger than 17 years of age.

Chemotherapy was the most common reason for catheter insertion. Restoration of CVC function was achieved in 177 patients (72%) within 120 minutes after the first dose. After instillation of a maximum of two doses of tenecteplase, CVC function was restored in 200 patients (81%), with similar frequencies in pediatric (83%) and adult (80%) patients. Adverse events (AEs) were reported in 31 patients (13%); fever (2%), neutropenia (1%), and nausea (0.8%) were most common. One serious AE, an allergic hypersensitivity reaction, was judged to be related to tenecteplase and/or a chemotherapeutic agent that the patient was receiving concurrently. Conclusions: Consecutive administration of one or two doses of tenecteplase into CVCs showed efficacy in the restoration of catheter function in patients with dysfunctional CVCs. © 2011 SIR.

Risk stratification for acute pulmonary embolism Kline J.A., Miller D.W.

JNCCN Journal of the National Comprehensive Cancer Network 2011 9:7 (800-810)

This article discusses state-of-the-art techniques for predicting risk of death after acute pulmonary embolism (PE), with special attention to how underlying malignancy adversely affects survival after an episode. Current methods of risk stratification generally categorize patients with PE as low-, moderate-, and high-risk for inhospital adverse outcomes of respiratory failure, circulatory shock, and death. Published risk stratification studies find that patients with PE and an underlying malignancy have a worse prognosis, but no validated risk stratification criteria have been published

specifically for these patients. Standard treatment is full-dose heparin followed by oral anticoagulation. The term escalated treatment refers to the use of systemic or intrapulmonary fibrinolytic agents, catheter-based treatment, or surgical embolectomy. Most patients with low-risk PE (normal vital signs and normal serum troponin, brain natriuretic peptide, and normal echocardiography) are treated successfully with standard anticoagulation, and many can be treated as outpatients. In contrast, patients with highrisk PE (systolic blood pressure < 90 mm Hg and no contraindications) often benefit from escalated treatment. Treatment decisions for patients with moderate-risk PE (normotension with evidence of right ventricular damage or dysfunction) are most controversial. Most patients in this category of risk recover with standard therapy, but some benefit from escalated treatment. Patients with cancer with an incidentally discovered PE should be risk stratified the same as those who have clinically suspected PE. © JNCCN-Journal of the National Comprehensive Cancer Network.

Stroke and the immune system: From pathophysiology to new therapeutic strategies

Macrez R., Ali C., Toutirais O., Le Mauff B., Defer G., Dirnagl U., Vivien Denis D. **The Lancet Neurology** 2011 **10:5** (471-480)

Stroke is the second most common cause of death worldwide and a major cause of acquired disability in adults. Despite tremendous progress in understanding the pathophysiology of stroke, translation of this knowledge into effective therapies has largely failed, with the exception of thrombolysis, which only benefits a small proportion of patients. Systemic and local immune responses have important roles in causing stroke and are implicated in the primary and secondary progression of ischaemic lesions, as well as in repair, recovery, and overall outcome after a stroke. However, potential therapeutic targets in the immune system and inflammatory responses have not been

well characterised. Development of novel and effective therapeutic strategies for stroke will require further investigation of these pathways in terms of their temporal profile (before, during, and after stroke) and risk-to-benefit therapeutic ratio of modulating them. © 2011 Elsevier Ltd.

Proteolytic networks in cancer

Mason S.D., Joyce J.A.

Trends in Cell Biology 2011 21:4 (228-237)

Proteases are important for multiple processes during malignant progression, including tumor angiogenesis, invasion and metastasis. Recent evidence reveals that tumor-promoting proteases function as part of an extensive multidirectional network of proteolytic interactions, in contrast to the unidirectional caspase cascade. These networks involve different constituents of the tumor microenvironment and key proteases, such as cathepsin B, urokinase-type plasminogen activator and several matrix metalloproteinases, occupy central nodes for amplifying proteolytic signals passing through the network. The proteolytic network interacts with other important signaling pathways in tumor biology, involving chemokines, cytokines, and kinases. Viewing these proteolytic interactions as a system of activating and inhibiting reactions provides insight into tumor biology and reveals relevant pharmaceutical targets. This review examines recent advances in understanding proteases in cancer and summarizes how the network of activity is co-opted to promote tumor progression. © 2010 Elsevier Ltd.

Record 29

Venous thromboembolism in the patient with cancer Lyman G.H.

Cancer 2011 117:7 (1334-1349)

Venous thromboembolism (VTE) is a significant cause of morbidity and mortality in patients with cancer. The risk of VTE varies over the natural history of cancer, with the highest risk occurring during hospitalization and after disease recurrence. Patient and disease characteristics are associated with further increased risk of VTE in this setting. Specific factors include cancer type (eg, pancreatic cancer, brain cancer, lymphoma) and the presence of metastatic disease at the time of diagnosis. VTE is a significant predictor of increased mortality during the first year among all types and stages of cancer, with metastatic disease reported to be the strongest predictor of mortality. VTE is also associated with early death in ambulatory patients with cancer. These data highlight the need for close monitoring, prompt treatment, and appropriate preventive strategies for VTE in patients with cancer. The American Society of Clinical Oncology and the National Comprehensive Cancer Network have issued guidelines regarding the prophylaxis and treatment of patients with cancer. This review summarizes the impact of VTE on patients with cancer, the effects of VTE on clinical outcomes, the importance of thromboprophylaxis in this population, relevant ongoing clinical trials examining the prevention of VTE, and new pharmacologic treatment options. Improved glycemic control induced by both metformin and repaglinide is associated with a reduction in blood levels of 3-deoxyglucosone in nonobese patients with type 2 diabetes
Engelen L., Lund S.S., Ferreira I., Tarnow L., Parving H.-H., Gram J., Winther K., Pedersen O., Teerlink T., Barto R., Stehouwer C.D.A., Vaag A.A., Schalkwijk C.G. European Journal of Endocrinology, Supplement 2011 164:3 (371-379)

Objective: Metformin has been reported to reduce a-dicarbonyls, which are known to contribute to diabetic complications. It is unclear whether this is due to direct quenching of a-dicarbonyls or to an improvement in glycemic control. We therefore compared the effects of metformin versus repaglinide, an antihyperglycemic agent with an insulinsecreting mechanism, on the levels of the a-dicarbonyl 3-deoxyglucosone (3DG). Methods: We conducted a single-center, double-masked, double-dummy, crossover study involving 96 nonobese patients with type 2 diabetes. After a 1-month run-in on diet-only treatment, patients were randomized to either repaglinide (6 mg daily) followed by metformin (2 g daily) or vice versa each during 4 months with a 1-month washout between interventions. Results: 3DG levels decreased after both metformin (-19.3% (95% confidence interval (CI): -23.5, -14.8)) and repaglinide (-20.8% (95% CI:-24.9,-16.3)) treatments, but no difference was found between treatments (1.8% (95% CI: -3.8, 7.8)). Regardless of the treatment, changes in glycemic variables were associated with changes in 3DG. Specifically, 3DG decreased by 22.7% (95% CI: 19.0, 26.5) per S.D. decrease in fasting plasma glucose (PG), by 20.0% (95% CI: 16.2, 23.9) per S.D. decrease in seven-point mean plasma glucose, by 22.5% (95% CI: 18.6, 26.6) per S.D. decrease in area under the curve for PG, by 17.2% (95% CI: 13.8, 20.6) per S.D. decrease in HbAlc, and by 10.9% (95% CI: 6.4, 15.5) per S.D. decrease in Amadori albumin. In addition, decreases in 3DG were associated with decreases in advanced glycation endproducts and endothelial markers. Conclusion: Improved glycemic control induced by both metformin and repaglinide is associated with a reduction in 3DG levels in nonobese individuals with type 2 diabetes. This may constitute a shared metabolic pathway through which both treatments have a beneficial impact on the cardiovascular risk. © 2011 European Society of Endocrinology.

Novel IkB kinase inhibitors for treatment of nuclear factor-kB-related diseases

Suzuki J.-I., Ogawa M., Muto S., Itai A., Isobe M., Hirata Y., Nagai R.

Expert Opinion on Investigational Drugs 2011 20:3 (395-405)

NF- κB is a key regulator of inflammation and immunity in cancer development. The I κB kinase (IKK) is a multisubunit complex containing catalytic subunits termed IKK- α , - β and - γ . It is well known that many pro-inflammatory stimuli require the IKK- β subunit for NF- κB activation. Areas covered: NF- κB affects the progression of inflammation-related diseases, such as myocardial ischemia, bronchial asthma, arthritis, cancer and other diseases. We review the characteristics and effects of these inhibitors on inflammatory and other diseases. Expert opinion: Various synthesized IKK inhibitors have been developed and they will be used clinically in the near future. © 2011 Informa UK, Ltd.

Improvement of hemodialysis catheter function with tenecteplase: A phase III, Open-label study: TROPICS 4

Fishbane S., Milligan S.L., Lempert K.D., Hertel J.E.W., Wetmore J.B., Oliver M.J., Blaney M., Gillespie B.S., Jacobs J.R., Begelman S.M.

Journal of Thrombosis and Thrombolysis 2011 31:1 (99-106)

Hemodialysis (HD) catheters are prone to thrombotic occlusion. We evaluated tenecteplase, a thrombolytic, for the treatment of dysfunctional HD catheters. Patients with tunneled HD catheters and blood flow rate (BFR) <300 mL/min received open-label tenecteplase (2 mg/lumen) for a 1 h intracatheter dwell. Treatment success was defined as BFR ≥300 mL/min and a ≥25 mL/min increase from baseline BFR, 30 min before and at the end of HD. Patients without treatment success at the end of the initial visit received another 2 mg dose of tenecteplase for an up to 72 h extended dwell. Of 223 enrolled patients, 34% (95% confidence interval [CI], 28-40%) had treatment success after a 1 h dwell. Mean (standard deviation [SD]) BFR change from baseline was 82 (124) mL/min. Treatment success in those who received extended-dwell tenecteplase (n = 116) was 49% (95% CI, 40-58%), with mean (SD) BFR change from baseline of 117 (140) mL/min. Reported targeted adverse events included five catheter-related bloodstream infections and one thrombosis. No intracranial hemorrhage, major bleeding, embolic events, or catheter-related complications were reported. Tenecteplase administered as a 1 h or 1 h plus extended dwell was associated with improved HD catheter function in the TROPICS 4 trial. © 2010 Springer Science+Business Media, LLC.

Neuroprotective drugs in traumatic CNS injury

Samantaray S., Thakore N.P., Matzelle D.D., Varma A., Ray S.K., Banik N.L. Open Drug Discovery Journal 2010 2:SPEC. ISS.3 (174-180)

Despite extensive experimental research, the numbers of neuroprotective drugs that have proven efficacy following treatment of patients with traumatic CNS injuries still remain meager. It would be worthwhile to emphasize that majority of the victims are mostly in the second or third decades of their lives. A survey on the neuroprotective molecules that has been tested experimentally and subsequently tried clinically has been found somewhat beneficial. In the present review, we consolidated the updates on a number of such drugs, which hold promise for therapy of traumatic CNS injuries. Two such agents, endogenous molecules estrogen and melatonin have been under investigation in our laboratory for their efficacy in experimental spinal cord injury in rats. © Samantaray et al.

Signatures of cardioembolic and large-vessel ischemic stroke

Jickling G.C., Xu H., Stamova B., Ander B.P., Zhan X., Tian Y., Liu D., Turner R.J., Mesias M., Verro P., Khoury J., Jauch E.C., Pancioli A., Broderick J.P., Sharp F.R. **Annals of Neurology** 2010 **68:5** (681-692)

Objective: The cause of stroke remains unknown or cryptogenic in many patients. We sought to determine whether gene expression signatures in blood can distinguish between cardioembolic and large-vessel causes of stroke, and whether these profiles can predict stroke etiology in the cryptogenic group. Methods: A total of 194 samples from 76 acute ischemic stroke patients were analyzed. RNA was isolated from blood and run on Affymetrix U133 Plus2.0 microarrays. Genes that distinguish large-vessel from cardioembolic stroke were determined at 3, 5, and 24 hours following stroke onset. Predictors were evaluated using cross-validation and a separate set of patients with known stroke subtype. The cause of cryptogenic stroke was predicted based on a model developed from strokes of known cause and identified predictors. Results: A 40-gene profile differentiated cardioembolic stroke from large-vessel stroke with >95% sensitivity and specificity. A separate 37-gene profile differentiated cardioembolic stroke due to atrial fibrillation from nonatrial fibrillation causes with >90% sensitivity and specificity. The identified genes elucidate differences in inflammation between stroke subtypes. When applied to patients with cryptogenic stroke, 17% are predicted to be large-vessel and 41% to be cardioembolic stroke. Of the cryptogenic strokes predicted to be cardioembolic, 27% were predicted to have atrial fibrillation. Interpretation: Gene expression signatures distinguish cardioembolic from large-vessel causes of ischemic stroke. These gene profiles may add valuable diagnostic information in the management of patients with stroke of unknown etiology though they need to be validated in future independent, large studies. New devices for treating acute ischemic stroke

Rosenberg N., Chen M., Prabhakaran S.

Recent Patents on CNS Drug Discovery 2010 5:2 (118-132)

The past decade has witnessed an explosion of devices available for treating acute ischemic stroke. Here, we review a range of recently patented devices and the data supporting their use. These include devices to enhance thrombolysis, thrombectomy devices, stents, devices for augmenting global brain tissue perfusion, and devices that provide neuroprotection after stroke. We discuss specific design elements of these devices and directions for future research. Ultimately, individually tailored combinations of these devices will likely prove most useful in treating patients with acute ischemic stroke. © 2010 Bentham Science Publishers Ltd.

Record 36

Repurposing an old drug to improve the use and safety of tissue plasminogen activator for acute ischemic stroke: Minocycline Hess D.C., Fagan S.C.

Pharmacotherapy 2010 30:7 PART 2 (55S-61S)

Tissue plasminogen activator (tPA) is the only drug approved by the United States Food and Drug Administration for treatment of acute ischemic stroke. Because the drug must be used soon after symptom onset and is associated with intracerebral hemorrhage, tPA remains underutilized. Research has therefore focused on identifying other drugs that can be used concomitantly with tPA to improve the odds of a favorable recovery and to reduce the risk of intracerebral hemorrhage. Minocycline is a broad-spectrum antibiotic that has been found to be a neuroprotective agent in preclinical ischemic stroke models. Minocycline inhibits matrix metalloproteinase-9, a biomarker for intracerebral hemorrhage associated with tPA use. Minocycline is also an antiinflammatory agent and inhibits poly(ADP-ribose) polymerase-1. Minocycline has been safe and well tolerated in clinical trials. Additional safety and efficacy data are needed, and a phase III trial of minocycline with tPA in patients experiencing acute ischemic stroke is planned.

Drug Terms

biological marker, doxycycline, fibrinolytic agent, gelatinase B, **minocycline**, n (5,6 dihydro 6 oxo 2 phenanthridinyl) 2 dimethylaminoacetamide, nicotinamide adenine dinucleotide adenosine diphosphate ribosyltransferase 1, nicotinamide adenine dinucleotide adenosine diphosphate ribosyltransferase inhibitor, nonsteroid antiinflammatory agent, tetracycline, tigecycline,

tissue plasminogen activator

Disease Terms

Gene expression profiling of blood for the prediction of ischemic stroke

Stamova B., Xu H., Jickling G., Bushnell C., Tian Y., Ander B.P., Zhan X., Liu D., Turner R., Adamczyk P., Khoury J.C., Pancioli A., Jauch E., Broderick J.P., Sharp F.R. **Stroke** 2010 **41:10** (2171-2177)

Background And Purpose-: A blood-based biomarker of acute ischemic stroke would be of significant value in clinical practice. This study aimed to (1) replicate in a larger cohort our previous study using gene expression profiling to predict ischemic stroke; and (2) refine prediction of ischemic stroke by including control groups relevant to ischemic stroke. Methods-: Patients with ischemic stroke (n=70, 199 samples) were compared with control subjects who were healthy (n=38), had vascular risk factors (n=52), and who had myocardial infarction (n=17). Whole blood was drawn \leq 3 hours, 5 hours, and 24 hours after stroke onset and from control subjects. RNA was processed on whole genome microarrays. Genes differentially expressed in ischemic stroke were identified and analyzed for predictive ability to discriminate stroke from control subjects. Results-: The 29 probe sets previously reported predicted a new set of ischemic strokes with 93.5% sensitivity and 89.5% specificity. Sixty- and 46-probe sets differentiated control groups from 3-hour and 24-hour ischemic stroke samples, respectively. A 97-probe set correctly classified 86% of ischemic strokes (3 hour+24 hour), 84% of healthy subjects, 96% of vascular risk factor subjects, and 75% with myocardial infarction. Conclusions-: This study replicated our previously reported gene expression profile in a larger cohort and identified additional genes that discriminate ischemic stroke from relevant control groups. This multigene approach shows potential for a point-of-care test in acute ischemic stroke. © 2010 American Heart Association, Inc.

The complexity of neurobiological processes in acute ischemic stroke

Brouns R., De Deyn P.P.

Clinical Neurology and Neurosurgery 2009 111:6 (483-495)

There is an urgent need for improved diagnostics and therapeutics for acute ischemic stroke. This is the focus of numerous research projects involving in vitro studies, animal models and clinical trials, all of which are based on current knowledge of disease mechanisms underlying acute focal cerebral ischemia. Insight in the chain of events occurring during acute ischemic injury is essential for understanding current and future diagnostic and therapeutic approaches. In this review, we summarize the actual knowledge on the pathophysiology of acute ischemic stroke. We focus on the ischemic cascade, which is a complex series of neurochemical processes that are unleashed by transient or permanent focal cerebral ischemia and involves cellular bioenergetic failure, excitotoxicity, oxidative stress, blood-brain barrier dysfunction, microvascular injury, hemostatic activation, post-ischemic inflammation and finally cell death of neurons, glial and endothelial cells. © 2009 Elsevier B.V. Transcranial ultrasound in clinical sonothrombolysis (TUCSON)

Molina C.A., Barreto A.D., Tsivgoulis G., Sierzenski P., Malkoff M.D., Rubiera M., Gonzales N., Mikulik R., Pate G., Ostrem J., Singleton W., Manvelian G., Unger E.C., Grotta J.C., Schellinger P.D., Alexandrov A.V.

Annals of Neurology 2009 **66:1** (28-38)

Objective: Microspheres (µS) reach intracranial occlusions and transmit energy momentum from an ultrasound wave to residual flow to promote recanalization. We report a randomized multicenter phase II trial of μS dose escalation with systemic thrombolysis. Methods: Stroke patients receiving 0.9mg/kg tissue plasminogen activator (tPA) with pretreatment proximal intracranial occlusions on transcranial Doppler (TCD) were randomized (2:1 ratio) to μS (MRX-801) infusion over 90 minutes (Cohort 1, 1.4ml; Cohort 2, 2.8ml) with continuous TCD insonation, whereas controls received tPA and brief TCD assessments. The primary endpoint was symptomatic intracerebral hemorrhage (sICH) within 36 hours after tPA. Results: Among 35 patients (Cohort 1 = 12, Cohort 2 = 11, controls = 12) no sICH occurred in Cohort 1 and controls, whereas 3 (27%, 2 fatal) sICHs occurred in Cohort 2 (p = 0.028). Sustained complete recanalization/clinical recovery rates (end of TCD monitoring/3 month) were 67%/75% for Cohort 1, 46%/50% for Cohort 2, and 33%/36% for controls (p = 0.255/0.167). The median time to any recanalization tended to be shorter in Cohort 1 (30 min; interquartile range [IQR], 6) and Cohort 2 (30 min; IQR, 69) compared to controls (60 min; IQR, 5; p = 0.054). Although patients with sICH had similar screening and pretreatment systolic blood pressure (SBP) levels in comparison to the rest, higher SBP levels were documented in sICH+ patients at 30 minutes, 60 minutes, 90 minutes, and 24-36 hours following tPA bolus. Interpretation: Perflutren lipid μS can be safely combined with systemic tPA and ultrasound at a dose of 1.4ml. Safety concerns in the second dose tier may necessitate extended enrollment and further experiments to determine the mechanisms by which microspheres interact with tissues. In both dose tiers, sonothrombolysis with µS and tPA shows a trend toward higher early recanalization and clinical recovery rates compared to standard intravenous tPA therapy. © 2009 American Neurological Association.

Ultrasound enhancement of fibrinolysis

Alexandrov A.V.

Stroke 2009 40:3 SUPPL. 1 (S107-S110)

Systemic administration of tissue plasminogen activator (tPA) remains the fastest way to initiate treatment for acute ischemic stroke. The presence of a proximal arterial occlusion should not be viewed as an insurmountable predictor of tPA failure. Because tPA works by induction of partial recanalization of large thrombi, early augmentation of fibrinolysis to improve recanalization is desirable. This augmentation is feasible and can be safely achieved at the bedside with diagnostic Doppler ultrasound. In the CLOTBUST trial, 83% of patients achieved any recanalization (46% complete, 27% partial) with

tPA+transcranial Doppler vs 50% (17% complete, 33% partial) with tPA alone within 2 hours of treatment (P<0.001). Sustained, complete recanalization at 2 hours was 38% vs 13%, respectively (f=0.03). A recent meta-analysis of 6 randomized and 3 nonrandomized clinical studies of sonothrombolysis showed that any diagnostic ultrasound monitoring can at least double the chance of early complete arterial recanalization at no increase in the risk of symptomatic intracerebral hemorrhage. Because application in humans of frequencies below the diagnostic range resulted in increased symptomatic bleeding rates, mechanisms by which megahertz and kilohertz frequencies interact with the clot-residual flow interface and endothelium are currently under renewed investigations. Catheter-based ultrasound delivery to arterial thrombi and intraventricular clots is the subject of ongoing clinical trials. Addition of gaseous perflutren-lipid microspheres to tPA and transcranial Doppler can further facilitate early flow improvement, with a 50% rate of early, complete recanalization in a recent feasibility study. Transcranial ultrasound delivery in an operator-independent and dosecontrolled manner is being tested in a clinical trial. © 2009 American Heart Association, Inc.

Effect of almonds on insulin secretion and insulin resistance in nondiabetic hyperlipidemic subjects: a randomized controlled crossover trial

Jenkins D.J.A., Kendall C.W.C., Marchie A., Josse A.R., Nguyen T.H., Faulkner D.A., Lapsley K.G., Singer W.

Metabolism: Clinical and Experimental 2008 57:7 (882-887)

Nuts appear to have a marked effect in cohort studies in reducing the risk of coronary heart disease (CHD), but their demonstrated ability to lower cholesterol can only explain a proportion of the reduction in risk. Our aim was to assess whether improvement in carbohydrate metabolism provides a further explanation for the effect of nuts in reducing CHD. The effects of whole almonds, taken as snacks, were compared with the effects of low saturated fat (<5% energy) whole-wheat muffins (control) in the therapeutic diets of hyperlipidemic subjects. In a randomized crossover study, 27 hyperlipidemic men and women consumed 3 isoenergetic (mean, 423 kcal/d) supplements each for 1 month. Supplements provided 22.2% of energy and consisted of full-dose almonds (73 \pm 3 g/d), half-dose almonds plus half-dose muffins, and full-dose muffins. Subjects were assessed at weeks 0, 2, and 4 and fasting blood samples were obtained. Twenty-four-hour urinary output was collected at the end of week 4 on each treatment. Mean body weights differed by less than 300 g between treatments. No differences were seen in baseline or treatment values for fasting glucose, insulin, Cpeptide, or insulin resistance as measured by homeostasis model assessment of insulin resistance. However, 24-hour urinary C-peptide output as a marker of 24-hour insulin secretion was significantly reduced on the half-and full-dose almonds by comparison to the control after adjustment for urinary creatinine output (P = .002 and P = .004, respectively). We conclude that reductions in 24-hour insulin secretion appear to be a further metabolic advantage of nuts that in the longer term may help to explain the association of nut consumption with reduced CHD risk. © 2008 Elsevier Inc. Almonds reduce biomarkers of lipid peroxidation in older hyperlipidemic subjects

Jenkins D.J.A., Kendall C.W.C., Marchie A., Josse A.R., Nguyen T.H., Faulkner D.A., Lapsley K.G., Blumberg J.

Journal of Nutrition 2008 138:5 (908-913)

Nut consumption has been associated with reduced coronary heart disease (CHD) risk. In addition to cholesterol-lowering properties, almonds have been shown to lower oxidized LDL concentrations. However, little is known regarding their effects on other markers of oxidative stress. The dose-response effects of whole almonds, taken as snacks, were compared with low-saturated fat (<5% energy) whole-wheat muffins (control) in the therapeutic diets of hyperlipidemic subjects. In a randomized crossover study, 27 hyperlipidemic men and women consumed 3 isoenergetic (mean 423 kcal/d or 1770 kJ/d) supplements each for 1 mo. Supplements consisted of full-dose almonds (73 ± 3 g/d), half-dose almonds plus half-dose muffins (half-dose almonds), and full-dose muffins (control). Subjects were assessed at wk 0, 2 and 4. Mean body weights differed ≤300 g between treatments, although the weight loss on the half-dose almond treatment was greater than on the control (P < 0.01). At 4 wk, the full-dose almonds reduced serum concentrations of malondialdehyde (MDA) (P = 0.040) and creatinineadjusted urinary isoprostane output (P = 0.026) compared with the control. Serum concentrations of α - or γ -tocopherol, adjusted or unadjusted for total cholesterol, were not affected by the treatments. Almond antioxidant activity was demonstrated by their effect on 2 biomarkers of lipid peroxidation, serum MDA and urinary isoprostanes, and supports the previous finding that almonds reduced oxidation of LDL-C. Antioxidant activity provides an additional possible mechanism, in addition to lowering cholesterol, that may account for the reduction in CHD risk with nut consumption. © 2008 American Society for Nutrition.

A pilot study of central venous catheter survival in cancer patients using low-molecular-weight heparin (dalteparin) and warfarin without catheter removal for the treatment of upper extremity deep vein thrombosis (The Catheter Study)

Kovacs M.J., Kahn S.R., Rodger M., Anderson D.R., Andreou R., Mangel J.E., Morrow B., Clement A.M., Wells P.S.

Journal of Thrombosis and Haemostasis 2007 5:8 (1650-1653)

Background: Central venous catheters in patients with cancer are associated with development of deep vein thrombosis (DVT); however, there is no accepted standard treatment. Objectives: To assess the safety and effectiveness of a management strategy for central venous catheter-related DVT in cancer patients consisting of dalteparin and warfarin without the need for line removal. Patients/methods: Patients older than 18 years of age with an active malignancy and who had symptomatic, acute, objectively documented UEDVT were eligible. Patients were treated with dalteparin 200 IU kg -1 per day for 5-7 days and warfarin with a target International Normalized Ratio of 2.0-3.0. Patients were followed for 3 months for recurrent venous thromboembolism, major hemorrhage and survival of the central venous catheter. Results: There were 74 patients (48 males). The average age was 58 years. There were no episodes of recurrent venous thromboembolism and three (4%) major bleeds. No lines were removed because of infusion failure or recurrence/extension of DVT. Conclusion: Treatment of UEDVTs secondary to central catheters in cancer patients with standard dalteparin/warfarin can allow the central line to remain in situ with little risk of line failure or recurrence/extension of the DVT. © 2007 International Society on Thrombosis and Haemostasis.

Drug Terms

dalteparin, low molecular weight heparin, warfarin

Disease Terms

catheter thrombosis, **deep vein thrombosis**, epistaxis, lung embolism, menorrhagia, recurrent disease, side effect, upper gastrointestinal bleeding, venous thromboembolism

Device Terms

central venous catheter

Other Terms
