5-dimensional Data Structure

x, y, z, t, i

A generalized parameter space based on observations across *C. elegans* embryos (x, y, z)

A spatially-independent parameter space ordered by A-P axial order (i) and lineage time (t, i)

Cell Division

Graph diameter expands (growth in number of nodes)

Local connectivity increases (nodal density)

Global modularity increases (differentiation events, bifurcation)

Initial
Condition

Expansion of Structure

Bipartite Structure
(Bifurcation)

Cell Division

Bifurcation: single network to bipartite.

- how many parts does the network fragment into over time?

Bipartite Structure
(Bifurcation)

Spatial Connectivity (Interactome)

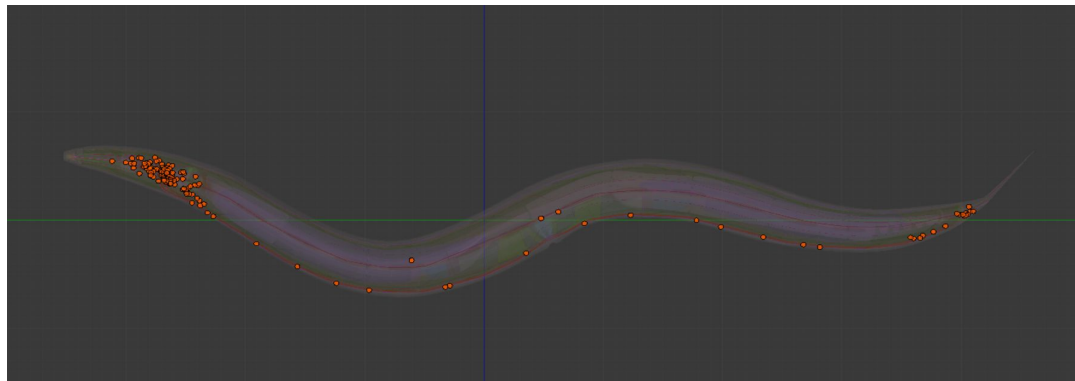

Spatial Connectivity (developmental lineages leading to Connectome)

Where connectome neurons emerge in the embryo

Generative Divergent Integration

8-cell example

Embryo network only. Connections between nodes:

For all developmental cells (blue), $< \text{distance } t$ (threshold) between cell centroids.

Sparse connectivity due to larger cell size.

24-cell example

Embryo and Neuronal network. Connections between nodes:

For all developmental cells (blue), $< \text{distance } t$ (threshold) between cell centroids.

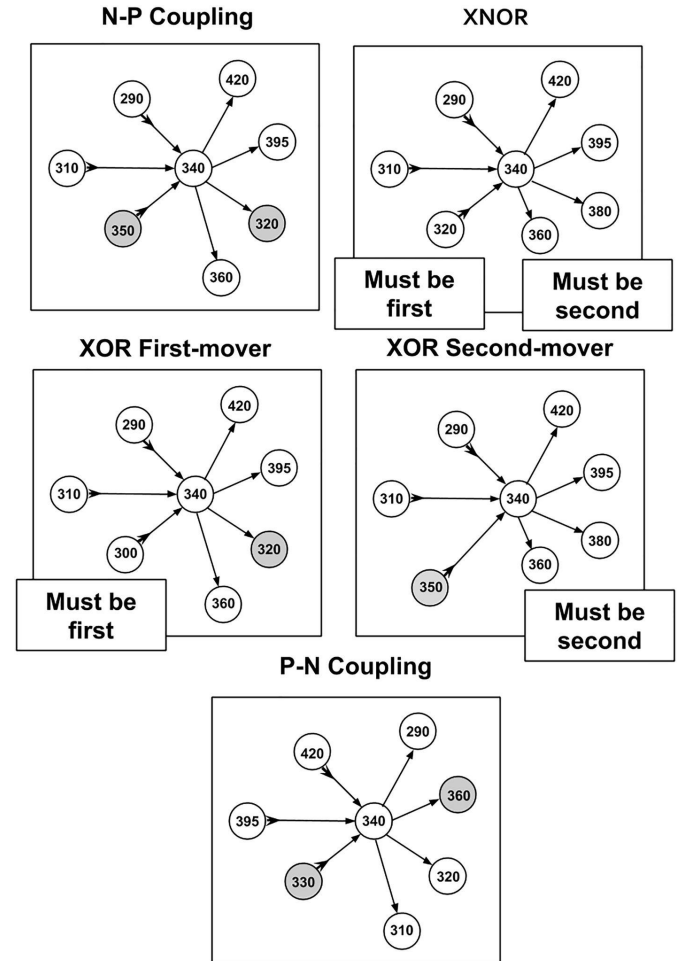

All neurons (green) that share gap junctions.

First-player Dynamics in Connectome Formation

Analysis of developmental synaptic connectivity data in *C. elegans*. Define connectogenetic strategies.

- potential pre- and post-synaptic relationships.
- yield various strategies for establishing connections.

Alicea, *Frontiers in Cellular Neuroscience*, 14, 524791. (2020).

Density-Bifurcation Model

The process of increasing connectivity in development is as follows:

- cells divide and migrate, connectivity increases.
- cell migration enriches local communities and cliques.
- function of cells diverges (differentiation), two interconnected networks emerge.
- interconnected networks provide weak ties (functional interdependencies) between emerging tissues.

Divergent Integration As Hyper-lineage Tree

A Hypergraph of Embryogenesis and Connectogenesis

LEFT: *C. elegans*-like connectome (deterministic lineage tree, bilateral symmetry).

Stem (developmental) cells can move across subgraphs (ovals, n = size of network), but terminally differentiated cells cannot.

Future directions: capturing embryo dynamics

- time-series of static embryo networks with spatially-localized differentiation.
