

## Supplementary Material

Ms. entitled “**A reproductive resilience index for pelagic fish in the southern Humboldt Current Large Marine Ecosystem**”

By: Andrés Ospina-Alvarez, Sebastián I. Vásquez, Ignacio A. Catalán, Susan Lowerre-Barbieri, Marcos Arteaga, Silvia de Juan.

### Section A

#### 1. A brief discussion about the Fishbase vulnerability index

The Fishbase vulnerability index is based on life-history traits such as species growth rate, life span and age at maturity and is available in Fishbase.org (Cheung et al., 2005). The vulnerability index is a fuzzy logic expert system and the application of its Boolean rules (i.e., “*If*”, “*then*”) often limits its use by natural resources’ managers (Strona 2014). According to FishBase, small fish with a rapid growth rate; short life span; and early reproduction, are the least vulnerable fish. However, the Fishbase approach underestimates species' vulnerability with small distributions (Strona 2014). Similarly, the Fishbase resilience index is based on selected biological parameters such as intrinsic rate of population growth, longevity, age at first maturity, fecundity and the von Bertalanffy growth parameter,  $K$ . allow to classify a fish population or species into categories of resilience or productivity used to assess threshold population levels for extinction. However, the Fishbase resilience index is strongly related to fecundity, which appears to be a poor indicator of vulnerability in marine fish to fishing (Sadovy, 2001).

Table S1. Fishbase intrinsic extinction vulnerability (vulnerability) and resilience to fishing pressure (FB's resilience) indexes. A detailed explanation of these indexes with their corresponding thresholds can be found in Cheung et al. 2005 and Musick 1999, respectively. The species are listed from lowest to highest value of vulnerability. The RRI proposed in this work is also presented.

Species	Vulnerability	Price category	FB's Resilience	Resilience remark	RRI mean
<i>Vinciguerrria lucetia</i>	10.00	unknown	High	Preliminary K or Fecundity	4.06
<i>Sprattus fuegensis</i>	14.30	high	High	K=0.7	3.37
<i>Engraulis ringens</i>	17.09	low	High	K=0.6-0.9; tm=1; tmax=3; Fec > 10,000	3.68
<i>Strangomera bentincki</i>	25.94	low	High	K=0.6	3.56
<i>Sardinops sagax</i>	34.17	low	Medium	K=0.45; tm=2; tmax=13-25; Fec=10,000	3.14
<i>Trachurus murphyi</i>	66.57	medium	Low	K=0.09-0.11; tmax=16	2.97
<i>Hoplostethus atlanticus</i>	72.86	medium	Very low	K=0.04-0.06; tm=5-33; tmax=140; Fec=10,000	1.94

## Section B

### **2. RRI in action: an evaluation over time and under different population size scenarios.**

To evaluate the RRI under different population size scenarios, we selected two coexisting species that have shown signs of temporal alternation in productivity: anchoveta (*Engraulis ringens*) and common sardine (*Strangomera bentincki*). As can be seen in Figure S1, since the mid-90s these species have shown two periods of contrasting population status: 2001-2007 and 2009-2016. In the first period, the anchoveta was the dominant species with spawning biomass levels that far exceeded the MSY, while the common sardine reached levels close to collapse. During the second period, the anchoveta steadily declined until collapsing, while the common sardine increased its spawning biomass above MSY. For each of these periods, the RRI was evaluated to analyse its response to different population scenarios and identify the reproductive biological traits involved in these changes.

These two species have been categorized as “data rich” because they have a formal structured stock assessment, annual acoustic cruises, estimation of spawning biomass evaluation through the daily egg production method and complementary studies such as coupled hydrodynamic-individual based models for the dispersive phases of the early life history. Under this consideration, we assign scores to each of the reproductive biological traits involved in the RRI through a metadata approximation for each selected period. These results and the source of information are summarized in Table S2.

In small pelagic fish, population abundance can vary by several orders of magnitude in a brief time in response to changes in environmental conditions that affect survival from hatching to recruitment. Small pelagic fishes are also extremely sensitive to climatic fluctuations as well as fishing pressure, which tend to impact the physiology and morphology of the fish, as well as their behaviour and distribution. Considering this plasticity, we hypothesize that the traits inferring reproductive resilience in small pelagic fishes are not invariant and will drive these changes.

Table S2. Reproductive traits scores for anchoveta (*Engraulis ringens*) and common sardine (*Strangomera bentincki*) in the HCLME for 2001-2007 and 2009-2016 periods. The selection of these periods is related to changes in population status (see Figure S1 for details). The sources correspond to databases and technical reports commissioned by the Chilean Undersecretariat of Fisheries to scientists and experts in the region with the aim of management. Some of these reports are available at [www.subpesca.cl](http://www.subpesca.cl). Some sources are related to indexed papers, which have been included in the list of references in this section.
