

### *Alterations from the published study protocol*

- Instead of defining a question on the participants' role at work, we decided to ask whether they have ever had contact with diabetes patients as healthcare providers.
- We included a question whether they have heard of ChatGPT, and if the answer was yes (adaptive questioning), whether they have used it.
- In the final version of the survey, it was not mandatory to answer the question on the participant's sex.
- The invitation was sent to 279 e-mail addresses on January 23, 2023, however due to an administrative issue, 47 e-mail addresses were missing from this list. These participants received the invitation 12-48 hours later, leaving them >48 hours to fill out the survey.
- After seeing strong associations between participant characteristics, we decided to include a multivariable model in addition to the univariable analyses to get a better picture of the effect of these on the outcome. The analytical approach allowed us to include all responses, also those who did not complete the entire survey (n=7).
