

Stochastic Multiatribute Acceptability Analysis: an application to the ranking of Italian regions

APPENDIX A

A.1 Multidimensional polarisation indices

The multidimensional Gini index has been developed as follows. We build upon the polarisation index proposed by Esteban and Ray (1994) corrected as proposed by Esteban *et al.* (2007). More precisely, with respect to the upward cumulative rank acceptability index $b_{\leq l}^k$, $l=1,\dots,n-1$, we computed the mean value $b_{\leq l}^M$ of the upward cumulative rank acceptability indices $b_{\leq l}^k$, $k=1,\dots,n$, that is

$$b_{\leq l}^M = \frac{\sum_{k=1}^n P_k b_{\leq l}^k}{\sum_{k=1}^n P_k}, \quad \text{eq. (A1)}$$

With P_k being the population of the k -th region, $k=1,\dots,n$. After we calculated the normalized upward cumulative rank acceptability indices $\tilde{b}_{\leq l}^k$, that is

$$\tilde{b}_{\leq l}^k = \frac{b_{\leq l}^k}{b_{\leq l}^M}. \quad \text{eq. (A2)}$$

On the basis of values $\tilde{b}_{\leq l}^k$, we defined the cumulative distribution $F^{\leq l} : [0,1] \rightarrow [0,1]$ such that for all $x \in [0,1]$

$$F^{\leq l}(x) = \frac{\sum_{k: \tilde{b}_{\leq l}^k \geq x} P_k}{\sum_{k=1}^n P_k}. \quad \text{eq. (A3)}$$

Following the methodology proposed by Aghevli and Mehran (1981) and Davies and Shorrocks (1989), we found also an optimal partition $\rho^{\leq l}$ of the distribution $F^{\leq l}$ in r groups minimise the Gini index value of within-group inequality, $r \leq n$, that is

$$\rho^{\geq l} = (z_0^{\geq l}, z_1^{\geq l}, \dots, z_{r-1}^{\geq l} \leq z_r^{\geq l} = 1; y_1^{\geq l}, \dots, y_r^{\geq l}; p_1^{\geq l}, \dots, p_r^{\geq l}) \quad \text{eq. (A4)}$$

with $0 = z_0^{\geq l} \leq z_1^{\geq l} \leq \dots \leq z_{r-1}^{\geq l} \leq z_r^{\geq l} = 1$ and $y_i^{\geq l}$ and $p_i^{\geq l}$ being the average value of the normalized cumulative rank acceptability indices $\tilde{b}_{\geq l}^k$ and the population shares in the interval $[z_{i-1}^{\geq l}, z_i^{\geq l}]$ of $\tilde{b}_{\geq l}^k$ values.

Finally we computed the polarization index $EGR^{\geq l}$ as follows:

$$EGR^{\geq l}(F, \alpha, \beta, \rho^{\geq l}) = \sum_{i=1}^r \sum_{j=1}^r \left(p_i^{\geq l} \right)^{1+\alpha} p_j^{\geq l} \left| y_i^{\geq l} - y_j^{\geq l} \right| - \beta [G(F) - G(\rho^{\geq l})] \quad \text{eq. (A5)}$$

with $\alpha \in [1, 1.16]$ is the sensitivity to polarization and $\beta \geq 0$. In our application to the study of Italian regions we considered 2 groups in the partition $\rho^{\geq l}$, $\alpha=1$ and $\beta=1$. Analogous polarization indices $EGR^{\geq l}$, $l=1, \dots, n-1$, can be defined with respect to the downward cumulative rank acceptability index $b_{\geq l}^k$.

A.2 Data and normalisation procedure

Table A.1 reports variables description along with summary statistics. Please note also that the last column of Table A.1 reports the categorization of each variable according the good/bad nature of the considered criteria.

Taking inspiration from Mazziotta and Pareto (2016), to make comparable variables expressed on different metric we normalised them according to the following formula

that assigns to each value x on a “good criterion”, that is a criterion with a preference increasing with respect to the assigned value (e.g. gross domestic product), the normalized value

$$\bar{x} = \begin{cases} 0 & \text{if } z \leq -3 \\ \frac{z+3}{6} & -3 < z < 3 \\ 1 & z \geq 3 \end{cases} \quad \text{eq. (A6)}$$

where z is the z-score

$$z = \frac{x - M}{\sigma} \quad \text{eq. (A7)}$$

with M and σ being the mean and the standard deviation of the considered criterion, respectively, so that

$$\bar{x} = \begin{cases} 0 & \text{if } x \leq M - 3\sigma \\ \frac{x - M + 3\sigma}{6\sigma} = 0.5 + \frac{z}{6} & \text{if } M - 3\sigma < x < M + 3\sigma \\ 1 & \text{if } x \geq M + 3\sigma \end{cases} \quad \text{eq. (A8)}$$

In case of a “bad criterion”, that is a criterion with a preference decreasing with respect to the assigned value (e.g. the social exclusion), the normalized value \bar{x} of x is given by

$$\bar{x} = \begin{cases} 1 & \text{if } z \leq -3 \\ \frac{3-z}{6} & -3 < z < 3 \\ 0 & z \geq 3 \end{cases} \quad \text{eq. (A9)}$$

that is,

$$\bar{x} = \begin{cases} 1 & \text{if } x \leq M - 3\sigma \\ \frac{M - x + 3\sigma}{6\sigma} = 0.5 - \frac{z}{6} & \text{if } M - 3\sigma < x < M + 3\sigma \\ 0 & \text{if } x \geq M + 3\sigma \end{cases} \quad \text{eq. (A10)}$$

The idea is to consider as extreme of the normalization scales the values $M-3\sigma$ and $M+3\sigma$ within which lie 99,73% of values in case of normal distribution and, by the Chebyshev's inequality, 89% of values for any distribution for which an average and standard deviation are defined.

For illustrative purposes, we begin with the evaluation according to the usual arithmetic mean (equal weights) of the performances normalized on the interval having as extreme the minimum and the maximum evaluations, that is

$$\tilde{x}_i = \frac{x_i - x_{min}}{x_{max} - x_{min}}; \quad \text{eq. (A11)}$$

in case of a “good criterion”, or

$$\tilde{x}_i = \frac{x_{max} - x_i}{x_{max} - x_{min}} \quad \text{eq. (A12)}$$

in case of a “bad criterion”.

A.3 Robustness checks

Stability of central weights.

We have tested the stability of the central weight vectors for the four regions for which is not null the probability to be the most preferred by computing the relative confidence factor. We proceeded as follows. We generated perturbed evaluations on considered criteria for all the regions by extracting random values in the interval

$$[g_i(a)-0.25\sigma_i, g_i(a)+0.25\sigma_i]$$

for the evaluations of each region a on considered criteria g_i , where σ_i is the standard deviation of the criterion g_i , $i=1,\dots,65$. Taking the central weight vector of the region a^* for which we test the stability of the weight vector giving it the best position, we computed the new ranking corresponding to the perturbed evaluations. We repeated this procedure 1,000,000 times and we got an estimation that the region a^* remains the best. This probability is 100% for Trentino Alto Adige, 87.2% for Toscana, 84.5% for Emilia Romagna and 80% for Friuli-Venezia Giulia.

Measurement error.

To test the robustness to measurement error we have taken in consideration perturbations in the values assigned to each region by the 65 variables of the BES dataset. More precisely, we considered an interval of variation

$$[g_i(a)-k\sigma_i, g_i(a)+k\sigma_i]$$

for the evaluations of each region a on considered criteria g_i , where σ_i is the standard deviation of the criterion g_i , $i=1,\dots,65$ and $k \geq 0$. The case $k=0$ corresponds to the absence of any perturbation. We further considered the case $k=0.25$, $k=0.5$ and $k=1$. In each one of these case and in each one of 1,000,000 of iterations we randomly extracted not only a vector of weights for the 65 criteria, but also a perturbed evaluation $\tilde{g}_i(a)$ in the considered range for each region a on each criterion g_i , $i=1,\dots,65$. On the basis of the perturbed values, for each one of the 65 criteria considered by BES, we computed the “perturbed mean” and the “perturbed standard deviation” and we normalized according to equations (8) and (9) the perturbed evaluations $\tilde{g}_i(a)$. The RF and the PWI corresponding to $k=0.25$ are shown in Table A.3 and Table A.4, respectively. The analogous tables for $k=0.5$ and $k=1$ can be found in the electronic appendix.

In order to assess the consistency and reliability of the resulting ranking, the Intraclass Correlation Coefficient (ICC) has been computed considering the above $k=0.25$, 0.5, and 1 as resulting from alternative evaluation exercises performed by 3 additional raters with respect to

the actual measurement released by the Italian National Institute of Statistics. To this end, the consistency-of-agreement ICC (CA-ICC) has been used. The rationale for adopting the CA-ICC is that different measurements are considered consistent if the scores from any two measurements (or *raters*) give the same ranking to all the regions (Shrout and Fleiss, 1979; McGraw and Wong, 1996a, 1996b). The results reported in Table A.4 show that our ranking exercise is robust to the substantial differences in measurement here hypothesised. Indeed, both the individual and the average coefficients are in no occasion¹ lower than 0.60 with 15 out of the 20 ranking here considered showing a ICC higher than 0.80.
