

A**B**

Suppl. Fig. 1. Normal oogenesis (**A**) and spermatogenesis (**B**). Note homologous chromosomes are divided in meiosis I and sister chromatids are divided in meiosis II. Some segments of homologous chromosomes may or may not exchange each other by crossing-over (CO) during meiosis I. Primary and secondary spermatocyte divide symmetrically at the sequential meiosis into four spermatozoa. In contrast, the division of the oocyte is asymmetric, and only one ovum is formed out of the four possibilities. PB1, first polar body; PB2, second polar body. * The PB1 may or may not divided at meiosis II; as shown here, it has not.

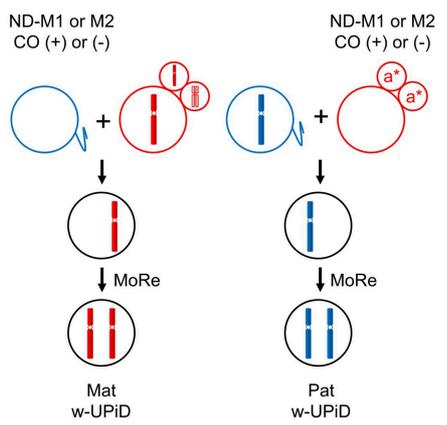

Suppl. Fig. 2. All possible consequences of nondisjunction during oogenesis (A) and spermatogenesis (B). Note predivision before meiosis I is omitted. CO, crossing-over; M1, meiosis I; M2, meiosis II; ND, nondisjunction.
