APPLICATION TO REAL DATASET

CONCLUSIONS

ACKNOWLEDGMENTS

We use Fourier filtering and equivalent layer technique to obtain the amplitude of the magnetic anomaly vector:

1. At high latitudes both methods yield excellent results;
2. At low latitudes some instabilities show up:
 - i. Artifacts and striations appear in the direction of declination;
 - ii. Synthetic tests and real dataset application shows that the equivalent layer technique is more stable.
3. The transformed amplitude of the magnetic anomaly vector indicates a possible correspondence with the local geology;
4. The inversion and qualitative interpretations of the amplitude of the magnetic anomaly vector (computed by the equivalent layer) can be used as an alternative to the traditional methods.

APPLICATION TO REAL DATASET

CONCLUSIONS

ACKNOWLEDGMENTS

We use Fourier filtering and equivalent layer technique to obtain the amplitude of the magnetic anomaly vector:

1. At high latitudes both methods yield excellent results;
2. At **low latitudes** some instabilities show up:
 - i. Artifacts and striations appear in the direction of declination;
 - ii. Synthetic tests and real dataset application shows that the **equivalent layer technique is more stable.**
3. The transformed amplitude of the magnetic anomaly vector indicates a possible correspondence with the local geology;
4. **The inversion and qualitative interpretations of the amplitude of the magnetic anomaly vector (computed by the equivalent layer) can be used as an alternative to the traditional methods.**
