The University of Leicester

2018

Declaration

I confirm that this research report is my original work. It has been submitted in the partial fulfilment for the degree of Doctorate in Clinical Psychology and no part of it has been submitted for any other degree or academic qualification.

This work has been checked for completeness prior to submission.

……

Craig Griffiths

Thesis abstract

Literature Review:

This portion of the thesis presents a systematic review and quantitative synthesis (including meta-analysis) of research pertaining to the behaviour of people diagnosed with CHARGE Syndrome. Results suggest that people with CHARGE are likely to present with issues associated with slower motor and adaptive skills development, intellectual disability, language modality, and eating behaviour. Elevated prevalence rates were also found for behaviours associated with a range of psychiatric diagnostic categories. Wide variability was observed in the individual presentation of people with CHARGE, reflecting the heterogeneity of physical manifestations. It is concluded that care should be taken in attributing individual behavioural traits to potential contributory factors.

Research Report:

The second part of the thesis describes an original research report investigating how the facial appearance of people with a range of genetic neurodevelopmental disorders (GNS) and autism spectrum disorder diagnosis (ASD) may affect *prima facie* personality trait judgments made by observers. Participants were shown merged face images representing GNS groups at age 12 and ASD diagnosed children at age 9, making trait ratings whilst an eye-tracker recorded viewing behaviour. Results suggested significant differences between trait judgments made between each face compared with a typically developing, age-matched control image. Eye-tracker results suggested differences in how GNS faces were processed with greater attention paid to areas of marked facial difference. Observations relevant to the clinical and social treatment of people with GNSs are discussed, as are implications for future research into face-based trait judgments.

Critical Appraisal:

A reflexive account is offered about the process of conducting the projects presented within this report, with particular attention to the clinical intent of the report and how that developed over time. Some reflection is offered on how this has changed the trainee's understanding and contributed to their development as a clinician.

Acknowledgments

I would like to thank those people associated with the DClinPsy course who have helped me along the path towards completing this work. In particular, to Alice Welham for supervising these projects, peer and SURG reviewers, Richard Kirkden for sharing the battles with the equipment, and the 2015 cohort who have shared this journey.

It seems important to acknowledge Megan Hollett, Shauna Benton and Jasmine Sanders for their pilot in their undergraduate projects, and to Professor Peter Hammond for providing materials. This report would not be in the shape that it is without these significant contributions.

I'd also like to thank my family for all their support. A special mention goes to my gramp, who instilled in me the value of education, and to my brothers for always being there for a friendly conversation about the stuff that really matters.

I am most grateful to my loving wife Holly, who has responded to my complaining, busyness, and irritability with patience, care, and empathy.

I'd thank the cats too, but they were only interested in getting in my way while I was trying to work.

The behavioural phenotype of CHARGE Syndrome: A systematic review of the literature

Abstract

The behavioural phenotype of CHARGE Syndrome: A systematic review of the literature

Craig Griffiths

CHARGE Syndrome is a neurodevelopmental syndrome with a consistent genetic aetiology but heterogeneous clinical presentation. Major diagnostic features include ocular coloboma, choanal atresia, cranial nerve dysfunction, and ear anomalies. Research with people diagnosed with genetic syndromes suggests that shared genetic attributes between individuals are in many cases associable with behavioural characteristics, with known gene-behaviour relationships referred to as behavioural phenotypes. This paper identifies and reviews relevant research to elucidate behavioural variables potentially associated with CHARGE syndrome. A systematic review of available literature, and quantitative synthesis in the form of pooled prevalence meta-analysis where possible, was conducted on 33 identified papers. Results suggest that people with CHARGE syndrome are likely to present with slower motor and adaptive skills development, intellectual disability, and issues associated with mode of communication and eating behaviour. Prevalence rates were higher than in typically developing people for behaviours associated with diagnoses of autistm spectrum disorder, attention deficit hyperactivity disorder, mood difficulties, obsessive-compulsive disorder, and aggression towards self and others. For the majority of measures, wide variability was observed between performances of individuals with CHARGE syndrome, reflecting the known heterogeneity of physical manifestations. Significant associations were found between certain behavioural traits and physical issues such as deaf-blindness. It is noted that care should be taken in attributing individual behavioural traits to potential contributory factors. Observations relevant to the clinical treatment of people with CHARGE syndrome are discussed, as are recommendations for future research.

Introduction

CHARGE Syndrome

CHARGE Syndrome (CHARGE) is a genetic neurodevelopmental syndrome first recognised in 1979 (Hall, 1979; Hittner *et al.*, 1979) and estimated to occur in around 1 in 8500 live births (Issekutz *et al.*, 2005). CHARGE is itself an acronym summarising key congenital anomalies co-occurring to varying degrees in affected individuals: coloboma (a congenital malformation of the eye affecting the iris, lens or retina); heart defect; atresia choanae (a congenital disorder causing blockage of the back of the nasal passage); retarded growth and development; genital hypoplasia; and ear anomalies/deafness. In addition to these factors there is also a suggestion CHARGE may have a unique behavioural phenotype (Lalani *et al.*, 2012).

Diagnosis of CHARGE is typically made according to clinical criteria that have undergone several revisions (Aloes *et al.*, 2001; Blake *et al.*, 1998; Pagon *et al.*, 1981; Verhoes, 2005). In Verhoes' criteria, three major or two major plus two minor features are required for typical CHARGE, with subtypes of partial and atypical CHARGE diagnosable for other combinations. Guidance suggests that any child presenting with coloboma, choanal atresia, or hypoplastic semi-circular canals should be considered for diagnosis of CHARGE (Hsu *et al.*, 2014). Table 1 presents the typical clinical features of CHARGE with prevalence estimates adapted from Lalani *et al*. (2012). This list is not exhaustive; the syndrome may present with other clinical problems such as immunodeficiency owing to DiGeorge sequence (Writzl *et al.*, 2007), dental problems (Strömland *et al.*, 2005), limb abnormalities (Brock *et al.*, 2003), scoliosis (Doyle & Blake, 2005), plus cognitive, speech or language delay (Lalani *et al.*, 2012).

Table 1 Clinical features in CHARGE syndrome

	Characteristics	Manifestations	Frequency
Major diagnostic features	Ocular coloboma	Coloboma of the iris, retina, choroid, disc; micophthalmos	80%-90%
	Choanal atresia or stenosis	Unilateral/bilateral: bony or membranous atresia/stenosis	50%-60%
	Cranial nerve dysfunction or anomaly	I: hyposmia or anosmia	90-100%[1]
		VII: facial palsy (unilateral of bilateral)	40%
		VIII: hypoplasia of auditory nerve	100%[2]
		IX/X: swallowing problems with aspiration	70%-90%
	Characteristic CHARGE syndrome ear	Outer ear: short, wide ear with little or no lobe, "snipped off" helix, prominent antihelix that is often discontinuous with tragus, triangular concha, decreased cartilage; often protruding and usually asymmetric	80%-100%
		Middle ear: ossicular malformations	
		Mondini defect of the cochlea	
		Temporal bone abnormalities; absent of hypoplastic semi-circular canals	
Minor diagnostic features	Genital hypoplasia	Males: micropenis, cryptorchidism	50%-60%
		Females: hypoplastic labia	
		Males and females: delayed puberty secondary to hypogonadotropic hypogonadism	90%[1]
	Developmental delay	Delayed milestones, hypotonia	≤100%
	Cardiovascular malformation	Including conotruncal defects, AV canal defects, and aortic arch anomalies	75%-85%
	Growth deficiency	Short stature, usually postnatal with or without growth hormone deficiency	70%-80%
	Orofacial cleft	Cleft lip and/or palate	15%-20%
	Tracheoesophageal fistula	Tracheoesophageal defects of all types	15%-20%
	Distinctive facial features	Square face with broad prominent forehead, prominent nasal bridge and columella, flat midface	70%-80%

[1]Estimates from The CHARGE Syndrome Foundation (2018)
[2]Estimate from Buchman *et al.* (2006)

Clinical diagnoses may be confirmed using gene analysis (see e.g. van Ravenswaaij-Arts *et al.*, 2015). A genetic basis of CHARGE was suspected after Tellier *et al.* (1998) found associations between the presence of CHARGE and higher mean paternal age at conception, alongside elevated concordance in monozygotic twins and rare familial cases. The genetic association has been confirmed in multiple studies (e.g. Husu *et al.*, 2013; Zentner *et al.*, 2010). A heterozygous mutation or deletion in the gene encoding chromodomain helicase DNA-binding protein 7 (CHD7) has been identified in 90-95% of people meeting clinical criteria (Hsu *et al.*, 2014). SEMA3E has been identified as a potential genetic factor in the past (Lalani *et al.*, 2004) but no longer appears on lists of genetic factors (Lalani *et al.*, 2012). There is no

indication that people showing clinical characteristics without CHD7 variation differ systematically from those who do, and clinical diagnoses are thus sometimes made even in the absence of CHD7 aberations.

Although the same genetic mutations are likely to be shared between most people receiving clinical diagnosis, CHARGE has an extremely heterogeneous presentation, such that one diagnosed individual may not share a majority of clinical features with another person sharing the diagnosis. Intellectual functioning, for example, may vary from average to IQ scores below 20 and whilst some people are considered deaf-blind, others have normal hearing and vision. This wide variation in characteristics can present difficulties for research and practice; the literature on CHARGE is replete with small case studies of atypical presentations of the condition and researchers of CHARGE must be conscious that no two individuals are necessarily alike. Variation may complicate life for people affected and their families (e.g. Wulffaert *et al.*, 2009), who are unlikely to have prior experience with CHARGE as 97% of CHD7 mutations occur with no family history (Sanlaville & Verloes, 2007).

Behavioural phenotypes

In addition to clarifying the physical manifestations of genetic abnormalities, advances in molecular genetics have made it possible to learn more about relationships between genetic factors and behaviour (Dykens & Rosner, 1999). The idea of a behavioural phenotype originated with Nyhan (1972) and has since been refined and garnered more interest as technology has improved. A behavioural phenotype is a set of motor, cognitive, linguistic and social characteristics that tend to be shared between individuals who can be assumed to share a genetic attribute (Flint & Yule, 1994). For a compelling case to be made for any feature to represent part of a behavioural phenotype, it must occur in one syndrome more than in others (Dykens & Hodapp, 2001).

Identifying behavioural phenotypes for specific conditions can have positive consequences. Firstly, greater awareness of behavioural patterns may facilitate faster recognition and diagnosis of conditions, leading to faster admission into services. Secondly, diagnosed individuals, their families, and services are likely to be affected by behavioural patterns, and better research may help each anticipate and prepare for atypical development. Knowledge that behaviour is part of a condition may help to externalise perceived causation for difficulties from the person and onto the condition itself, and thereby arguably help families cope with specific behavioural challenges. Finally, identification of behavioural phenotypes may itself lead to the elucidation of the genetic influences on behaviour, contributing to scientific understanding (Flint, 1998).

Conclusively identifying a behavioural phenotype for any given syndrome is fraught with difficulty. Behaviours are likely to develop through gene-environment interactions in which the physical characteristics of each individual form an idiosyncratic part of their physical reality (Taylor & Oliver, 2008). Flint (1998) identified that even in relatively simple situations sample sizes of over 100 may be required to find statistical significance for behaviours that occur in fewer than 25% of cases. Also, for CHARGE, in which people present with multiple congenital anomalies, clarifying whether a behaviour is due to one feature of the condition or another may be difficult. Certainly, it is important to compare reported behavioural features against data on behaviours associated with relevant deficits to ensure the two are differentiated and the relationship between physical features (including genetic aberrations) and behaviour is clearly delineated. It is also crucial that researchers employ well-matched control groups to aid in comparison between similar groups, such as people with comparable levels of cognitive functioning, as some behaviours are generally seen more frequently with intellectual disability.

Despite complexities, it has been possible to develop reliable and valid behavioural profiles for a range of genetic syndromes. One of the more common genetic syndromes, Down syndrome, has an associated behavioural phenotype that includes: slower cognitive development; language delay; charming, affectionate, and outgoing social behaviour; and delayed motor development (Fidler *et al.*, 2009). Behavioural phenotypes require careful exploration and an appreciation of complexity; a diagnosable condition (such as autism spectrum disorder, or ASD) identified in people with one syndrome may differ in how it presents for that group than others. One syndrome group with a known association with ASD diagnosis may display a different pattern (or profile) of behaviours to people from a different syndrome group with the same diagnostic association, limiting the ease of direct comparability in syndrome groups and raising questions about the diagnostic concepts commonly applied to these groups (Moss & Howlin, 2009; Moss *et al.*, 2013).

CHARGE does not currently have a clearly delineated behavioural phenotype, and there has, to the author's knowledge, been no prior systematic attempt at synthesising research. There are, however, many behaviours which have been reported to be common in the syndrome. Lalani *et al.* (2012) list repetitive, obsessive-compulsive, aggressive, and self-abusive behaviours, as well as patterns of behaviour often associated with the 'ADHD' label. Identifying a behavioural profile for CHARGE is complicated by the wide range of variability in presentation and by the severely disabling effects of associated symptoms. Any behaviours recognised may represent attempts at communication (Brown, 2005; Salem-Hartshorne & Jacob, 2005), result from sensory disability (Hartshorne & Cypher, 2004), be due to other associated developmental problems such as 'ASD' (Johansson *et al.*, 2006), or be caused by repeat childhood hospitalisation (Vervloed *et al,* 2006).

This review aimed to further the delineation of a behavioural phenotype for people with CHARGE by systematically identifying and reviewing available literature on the behaviour

of people with CHARGE. It was hoped that this would help researchers, clinicians, and the families and individuals affected, to gain a clear reference point through which they may better understand behaviours and associated difficulties.

Method

Search strategy

A systematic review of research literature databases was completed to identify research articles that might pertain to the review aims. The PSYCInfo, MEDLINE, and EMBASE databases were selected to include research from psychological, medical, genetic, and healthcare disciplines. Appendix B presents rationales for database selection.

Title and abstract search terms were developed based on topics pertaining to the two main aspects of the review question: CHARGE and behaviour (summarised in Table 2). CHARGE terms were taken from the Online Mendelian Inheritance in Man (OMIM) website (OMIM, 2017). Behaviour terms were developed reflexively with the literature, to cover features of behaviour, cognition, emotion, ability, language, sensory function, and development; many terms were included to maximise sensitivity.

Table 2 Search terms used

CHARGE	Behaviour	
CHARGE Association*	Behavio*	Infant
CHARGE Syndrome*	Psych*	ASD
Hall-Hittner	Emotion*	Repetiti*
HHS	Cognit*	Ritual*
CHD7	Phenotyp*	Stereotyp*
SEMA3E	Abilit*	Social
[Coloboma AND Heart anomaly AND Choanal Atresia AND Retardation AND "Genital and Ear Anomalies"]	Learning	Sociability
	IQ	Anxi*
	Intell*	Mood
	Retardation	Depressi*
	Processing	Affect*
	Development*	Sensory
	Language	Sleep
	Linguistic	Memory
	Communicat*	Executive function*
	Speech	Function*
	Verbal	Adaptive
	Motor	Maladaptive
	Psychomotor	Self-injur*
	Autis*	Self-harm
	Child	Personalit*

Database search options were used to limit results to those published: in academic journal articles to ensure quality and scientific rigor; in the English language; and since 1979 to keep results relevant to the association as recognised by Hall and Hittner.

The literature search of titles and abstracts generated 3285 articles. Of these, 236 were produced in PSYCInfo, 1628 in MEDLINE, and 1421 in EMBASE, (Appendix C). These 3285 articles were exported to RefWorks where duplicates were identified and removed, leaving 1777 articles.

Shortlisting process

Title and abstract screening was completed according to set inclusion and exclusion criteria. Criteria were applied hierarchically according to Table 3 such that each article must pass through the first criterion before being considered against the second, then third and so on. Articles excluded because they had 10 or fewer participants or presented case studies

were retained and processed separately (Appendix D); they are not included in the following review. Through the process of title and abstract screening an additional 49 duplicates were identified and removed

Table 3 Articles removed by application of inclusion and exclusion criteria

	Criterion	Removed
Inclusion	Article must be an original research study of any design	244
	Article must be published in a peer-reviewed journal	0
	Article must only involve human participants, or be designed such that human data can be extracted from data from other sources	120
	Article must only concern people with CHARGE syndrome, or be designed such that CHARGE syndrome data can be extracted from data from other sources	1025
	Article methodology must investigate some aspect of behavioural phenotypes. This may include: motor, linguistic, cognitive, emotional, or social development or behaviour. Where articles also investigate physical features and/or biological and genetic mechanisms, behavioural data must be presented such that it can be extracted clearly	236
Exclusion	Article must not be an intervention study and designed such that pre-intervention data may not be clearly extracted	11
	Article must not only investigate prevalence of the CHARGE syndrome	1
	Article must not only investigate a service	0
	Article must not only investigate physical features of CHARGE	20
	Article must not have 10 or fewer participants or present only a case study or series of case studies (processed separately)	25

At the end of this process, 46 papers remained. Reference sections of the remaining papers and citations listed on databases were checked for additional articles that may have been missed in the main search. This process identified four new papers (Abi Daoud *e al.*, 2002; Jure *et al.*, 1991; Souriau *et al.*, 2005; Wiznitzer *et al.*, 1987). The final total of articles assessed as meeting all inclusion criteria was 50 (Appendix E).

Full versions of the remaining 50 articles were obtained and individually screened. Articles were read in full and rechecked against inclusion and exclusion criteria. Reapplying inclusion and exclusion criteria caused a further 14 articles to be removed.

Quality appraisal

All 36 remaining papers were then assessed for quality. Quality rating criteria designed to control for low-validity research were adapted from Richards *et al.* (2015). Criteria were for sample identification, confirmation of CHARGE syndrome, tools used to assess symptomatic and behavioural features, and comparison group. Figure 1 presents the criteria as applied. To provide a simple visual matric of evidence quality, each article received one rating colour code for each of the four criteria, either: red if scored 0, orange if scored 1, amber if scored 2, and green if scored 3. The comparison or control group criterion was applied reflexively with the methodology of each individual paper; where no comparison or control group was appropriate to the design the criterion would be marked n/a and removed from score calculations. Where no comparison or control data were offered but results could be compared with readily-available and published TD norms the ratings were made against the quality of these norms. The maximum quality score per article was 12. A score between 0 and 1 was calculated for each paper by dividing the attained score by the maximum possible score; all papers scoring 0.33 or higher were included. Multiple ratings were made for papers that employed multiple methodologies (thus, in theory, an article could "pass" for one area of assessment but "fail" for another). Three articles (Abi Daoud *et al.*, 2002; Blake & Brown, 1993; Lieberman *et al.*, 2012) failed to reach minimum quality criteria and were removed from the review. Figure 2 presents a PRISMA diagram summarising papers removed at each stage (Moher et al., 2009). At the end of this process 33 papers remained for full review.

	Quality Rating			
	0 - Poor	**1 - Adequate**	**2 – Good**	**3 - Excellent**
Sample Identification	Not specified/reported	Single restricted or non-random sample e.g., a specialist clinic or previous research study[1] Single regional sample e.g., regional support groups.	Multiple restricted or non-random samples e.g., multi-region specialist clinics National non-random sampling e.g., national parent support groups.	Random or total population sample.
Confirmation of syndrome	Not confirmed/reported Clinical diagnosis only suspected	Clinical diagnosis by 'generalist' e.g., GP or Paediatrician, or not stated.	Clinical diagnosis by 'expert' e.g., Clinical Geneticist or Specialist Paediatrician.	Molecular/Cytogentic/ Metabolic confirmation of diagnosis.
Assessment of characteristic	Not specified/reported	Self/informant-report only, bespoke data collection methods.	'Generalist' clinical judgement only, or clinical instrument completed by non-professional, including self/informant.	Specialist clinical judgement and/or at least one clinical instrument completed by a professional.
Comparison/control group	Comparison group is not matched at all[1]; only matches age on adult/child basis; or includes measure norms from TD population without more specific matching.	Comparison group – a little relevant matching[1]; includes measure norms where some degree of matching is possible (one or two low-relevance matching variables).	Well-matched[1] comparison group (two+ low-relevance matching variables or one high-relevance matching variable).	Very well-matched[1] comparison group (two+ high-relevance matching variables or one high-relevance variable with at least one low-relevance variable).

[1]Matching variables Low-level: age, gender; High-relevance: ability level, sensory disability, physical disability,

Figure 1 Quality Criteria

[1] For individuals recruited as part of a larger *ongoing* study, if the recruitment strategy is described, it is coded. If not, it is coded as 1, indicating the sample has come from one source (i.e., the larger ongoing study).

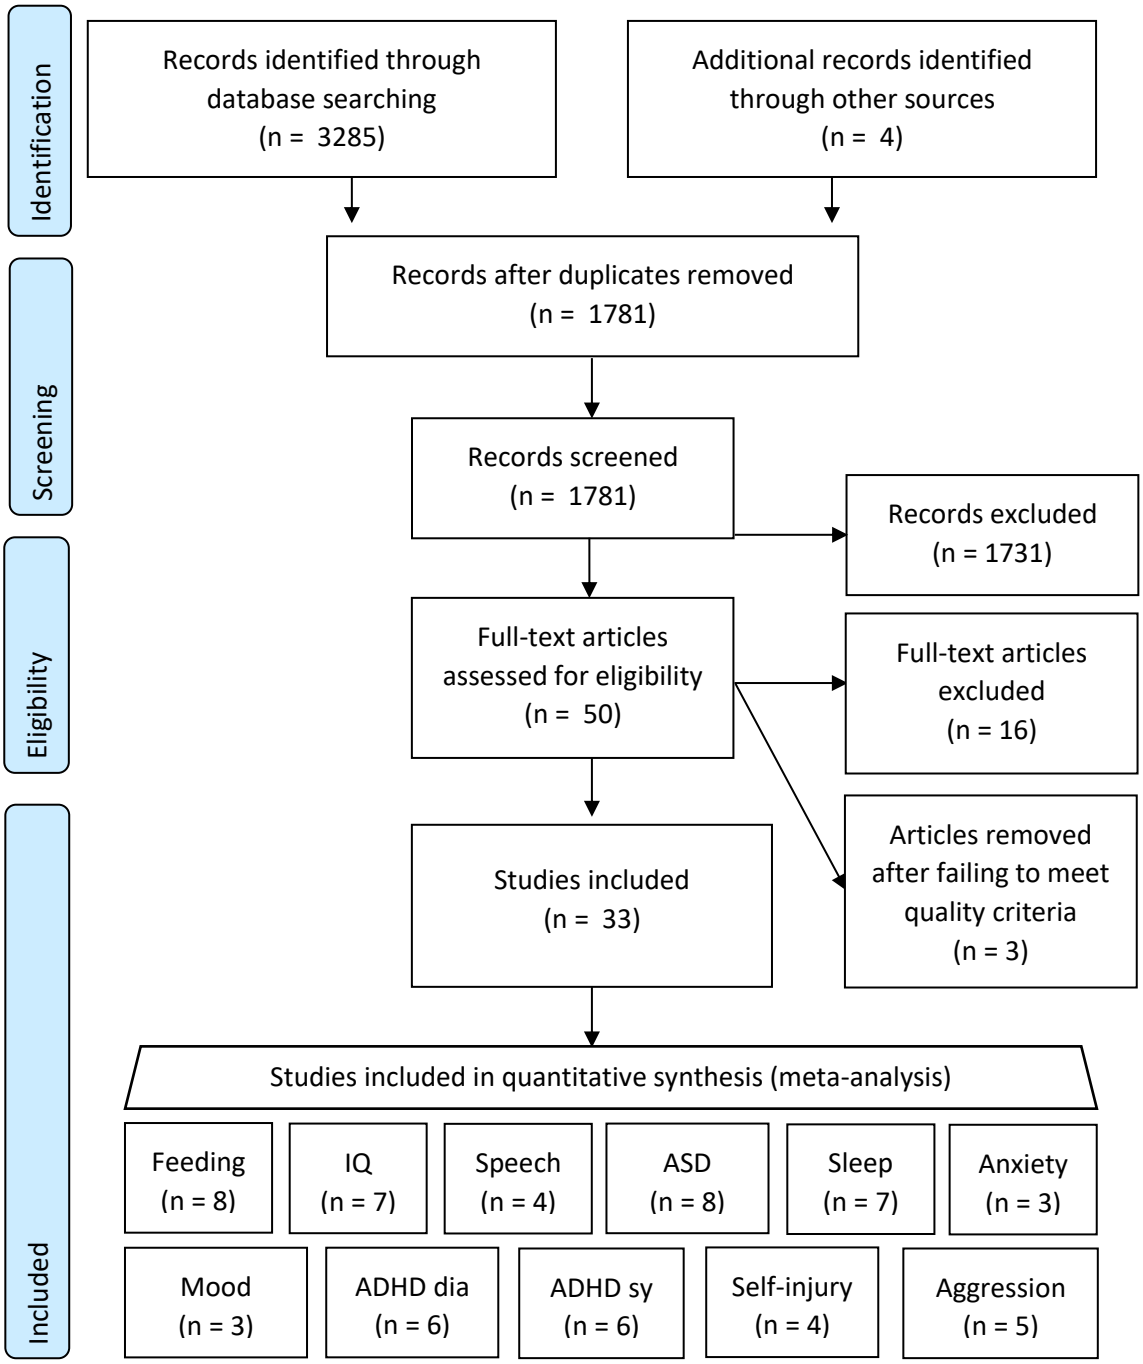

Figure 2 PRISMA Flow Diagram

Data analysis

Meta-analysis of the prevalence of a number of characteristics (feeding difficulties, intellectual disability, verbal speech modality, ASD diagnosis, sleep difficulties, anxiety difficulties, mood difficulties, ADHD diagnosis, ADHD symptomatology, self-injury, and aggression to others) was conducted. Data were analysed using MetaXL v.5.3 (Baredregt & Doi, 2016) to generate estimates of pooled prevalence. A random effects model was selected

for this analysis. This model assumes two sources of variability: 1) sampling error; and 2) differences at the level of the studies. It aims to control for these in the weightings assigned to each study. This contrasts with a fixed effects model, which assumes that all differences between studies are a function of sampling error and was not considered suitable for the current data given the apparently large variability in the prevalence and nature of reported characteristics in the studies. The random effects model does not account for differences in quality between studies, so a quality-effects model was also generated using quality ratings described, which research suggests maintains a correct coverage probability of the confidence interval and to be robust to subjectivity in quality assessment (Doi *et al.*, 2015). Meta-analysis data tables are presented in Appendix F.

Results

General and motor development

Ten papers reported on general development. Developmental delay was observed in between 80-85% (Husu *et al.,* 2013; Strömland *et al.,* 2005) and 100% (Hudson *et al.*, 2016), though diagnosis of pervasive developmental disorder occurred in only 13% of 87 people according to Wachtel *et al.* (2007). Functioning levels were generally low, with several studies finding that most score three standard deviations below TD averages (Abadie *et al.,* 2000; Salem-Hartshorne & Jacob, 2004; 2005; Santoro *et al,* 2014). Strömland *et al.* (2005) found 'profound deficits' in 35% and 'mild/moderate deficits' in 18%. Wulffaert *et al*. (2009) reported an adaptive functioning range between 0.2 and 8.6 years for a chronological age range of 1.7-22.2 years. There were greater differences for older participants as the capabilities of TD children moved away from those achievable for most people with CHARGE (Salem-Harshorne & Jacob, 2005; Santoro *et al*., 2014). Prevalence of health problems was associated with greater delay (Vervloed *et al.,* 2006).

Twelve papers reported on attainment of gross motor skills. Delayed motor milestones were observed for almost all children with CHARGE (Hartshorne *et al.,* 2007; 2005; Husu *et al.,*

2013). Raqbi *et al.*, (2003) found that the average developmental quotient for children aged zero-four was 50, suggesting markedly delayed development, with most displaying global impairment. Gross motor skills appear to be weaker than fine motor skills (Haibach & Lieberman, 2013; Santoro *et al.*, 2014). Regarding average age ranges within which walking has been observed to be achieved (Table 4), the latest mean estimate for TD was six months sooner than the earliest estimate for people with CHARGE, suggesting substantial differences. Delays of at least one year for walking are suggested.

Table 4 Observed average ages at which people with CS achieved motor milestones

Motor skill	Mean age	Article	N	SI[2]	CS	AC	GC	TD estimates[1]
Crawling	19 m	Hartshorne *et al.* (2007)	98					9-12 months
Walking	2-3 yr	Abadie *et al.* (2000)	17					
	3-4 yr	Dammeyer (2012)	17					10-18 months
		Haibach & Lieberman (2013)	21					
		Harsthorne *et al.* (2007)	98					
		Hartshorne *et al*. (2016)	53					
		Hartshorne & Cypher (2004)	100					
		Salem-Hartshorne & Jacob (2005)	85					
	4+ yr	Blake *et al.* (2005)	30					
		Hartshorne & Cypher (2004)	100					
		Salem-Hartshorne & Jacob (2005)	85					

[1] Estimates from NHS Choices (2018)

Three papers offered information regarding the relationship between development and age of gross motor milestone acquisition. Age of walking was correlated with Behaviour Rating Inventory of Executive Function (BRIEF) index scores (r=.23-.29, p<0.05; in Hartshorne et al., 2007), and Adaptive Behaviour Evaluation Scale raw scores (r=.39, p<.01 in Salem-Hartshorne & Jacob, 2004; r=.55, p<.01 in Salem-Hartshorne & Jacob, 2005).

Balance was associated with difficulty achieving gross motor skills. Vestibular difficulties were present in up to 87.5% of children (Johansson *et al.,* 2006; Strömland *et al.,* 2005), though higher quality studies produced lower estimates (77% in Husu *et al.,* 2013; 44%

[2] Coloured columns correspond to quality criteria in Figure 1.

in Issekutz *et al.,* 2013). Fifty-seven percent of children with CHARGE were at medium to high risk of falls (Haibach & Lieberman, 2013), tending to perform better in familiar places with stable footing (Abadie *et al.,* 2000; Haibach & Lieberman, 2013; Souriau *et al.,* 2005). Confidence is another factor; Haibach & Lieberman (2013) found that all children with CHARGE reported 0/10 confidence in their balance for any activity.

Adaptive skills/activities of everyday living

Blake *et al.* (2005) and Hartshorne *et al.* (2016) reported on how many people in their sample had achieved functional independence in key developmental areas (Table 5). These suggest a significant minority of people with CHARGE do not achieve independence in basic tasks and demanding tasks are achieved by a small minority. As elsewhere, the range of observed ability varied widely; where mean age of toileting was 5.5 years, standard deviation was 3.1 years (Blake *et al.*, 2005). Santoro *et al.* (2014) provided a range of relevant developmental quotient data suggesting developmental quotients of: ~30% for feeding, dressing, toileting, and communication; and ~75% for washing themselves. Deficits were most pronounced for people aged over three years. Younger people scored lowest relative to peers in health and self-care, though these areas became a relative strength with age (Salem-Hartshorne and Jacob, 2004; 2005).

Table 5 Percentages of people with CHARGE achieving levels of independence for activities

Article	N	Quality				Independence level	Toileting	Dressing	Washing	Cleaning	Travelling	Shopping	Cooking	Finances
		SI	CS	AC	GC									
Blake *et al.* (2005)	30					None	33	33	33	41	56	66	57	86
						Little/Some	13	6	23	38	11	21	43	10
						Most/All	53	60	43	20	30	13	0	3
Hartshorne *et al.* (2016)	53					None	9	8	15	32	58	52	43	68
						Little/Some	23	31	34	43	19	35	43	23
						Most/All	68	62	51	25	22	12	13	9

Nine studies reported on eating difficulties, eight of which suggested elevated prevalence for people with CHARGE (Table 6). Pooled prevalence estimates based on feeding

and swallowing difficulties together suggested that such difficulties may exist in 71% to 83% (95% confidence interval) of people (Figure 3). Where described, swallowing problems were relatively severe (MacDonald *et al.,* 2017). Issekutz *et al.* (2005) associated bilateral posterior choanal atresia with fewer chewing and swallowing issues, and more major clinical characteristics with a greater number of difficulties. In addition, Hudson *et al.* (2016), in a lower-quality study focused on feeding, reported that 95% over-stuffed their mouths with food and 30% held food in their mouths for hours. Eating difficulties may not be more prevalent overall than for children with other developmental disorders but may vary depending upon physical malformations present. This was associated with mouth under-sensitivity and reflexive processes where fear and defensiveness became associated with mealtimes due to negative impacts on relationships (Hudson *et al.,* 2016).

Table 6 Observed prevalence rates of eating difficulties for people with CHARGE

Difficulty	Rate	Article	N	Quality				Other estimates[1]

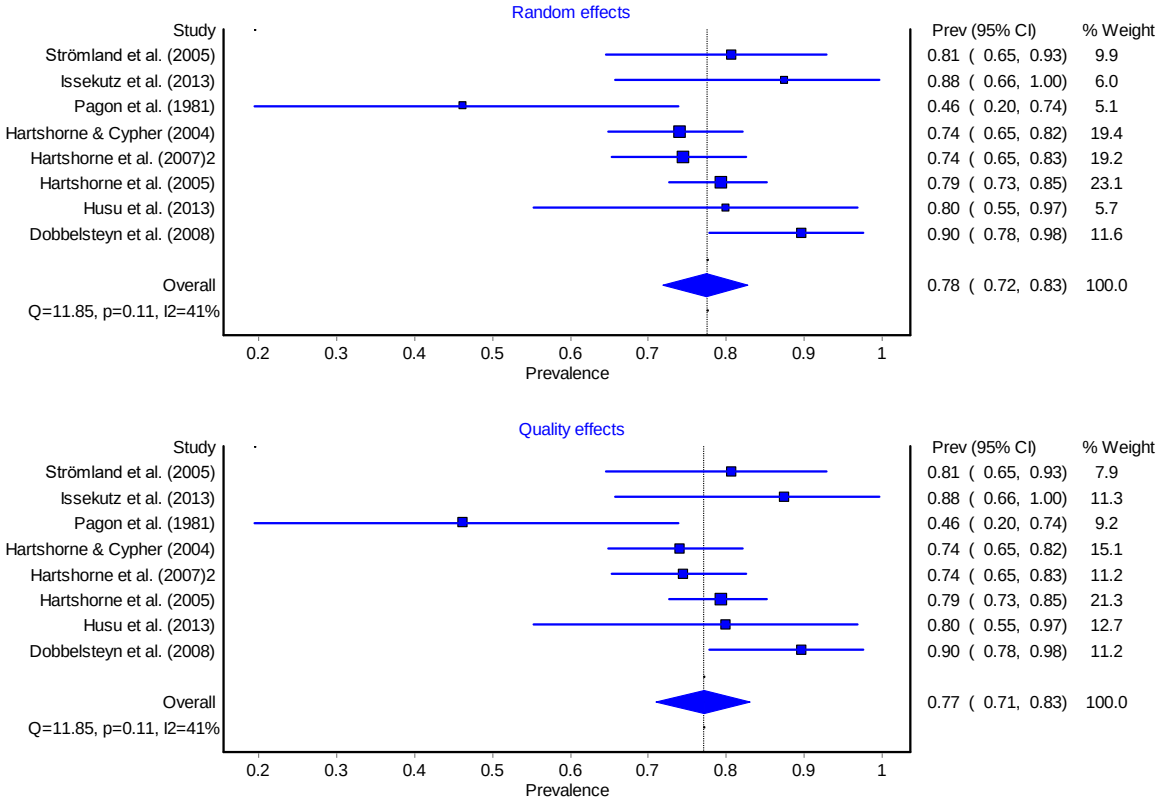

Figure 3 Pooled prevalence estimates of feeding and swallowing difficulties

Activity levels amongst people with CHARGE were described in two papers. These found levels were significantly lower than for TD people (Forward *et al.,* 2007), equivalent to people with Down and Williams syndromes, and higher than people with Prader-Willi syndrome (Graham *et al.,* 2005). Three studies looked at range of and preference for certain activities: Graham *et al.* (2005) found no evidence for a restricted set of activities and interests whilst Hartshorne *et al.* (2016) and Souriau *et al.* (2005) observed that physical and sensory ability influenced preferences.

Cognitive development and executive functioning

Nine papers reported on intellectual functioning, seven reporting IQ score estimates (Table 7). Pooled prevalence estimates suggested 52-81% (95% confidence interval) may present with an IQ below 70 (Figure 4). Pagon *et al.* (1981) found 19% of 21 people had 'profound retardation' and Souriau *et al.* (2005) that 59% of 71 had difficulty with 'complex information.' IQ score ranges varied widely. Santoro *et al.* (2014), using an adapted measure of child development, found that cognitive skills in children under three years-old had a

developmental quotient range of <10-130, with a median of 65. Intellectual ability correlated negatively with visual impairment, microcephaly, and brain malformation (Johansson *et al.,* 2006; Raqbi *et al.,* 2003). Hartshorne *et al*. (2007) presented data on executive functioning; a majority had clinically insignificant scores but mean scores were elevated, indicating greater difficulty, except in 'organisation of materials.' Over half had high scores on Shift, Monitor, and Behavioural Regulation indices, the latter correlating positively with deaf-blindness.

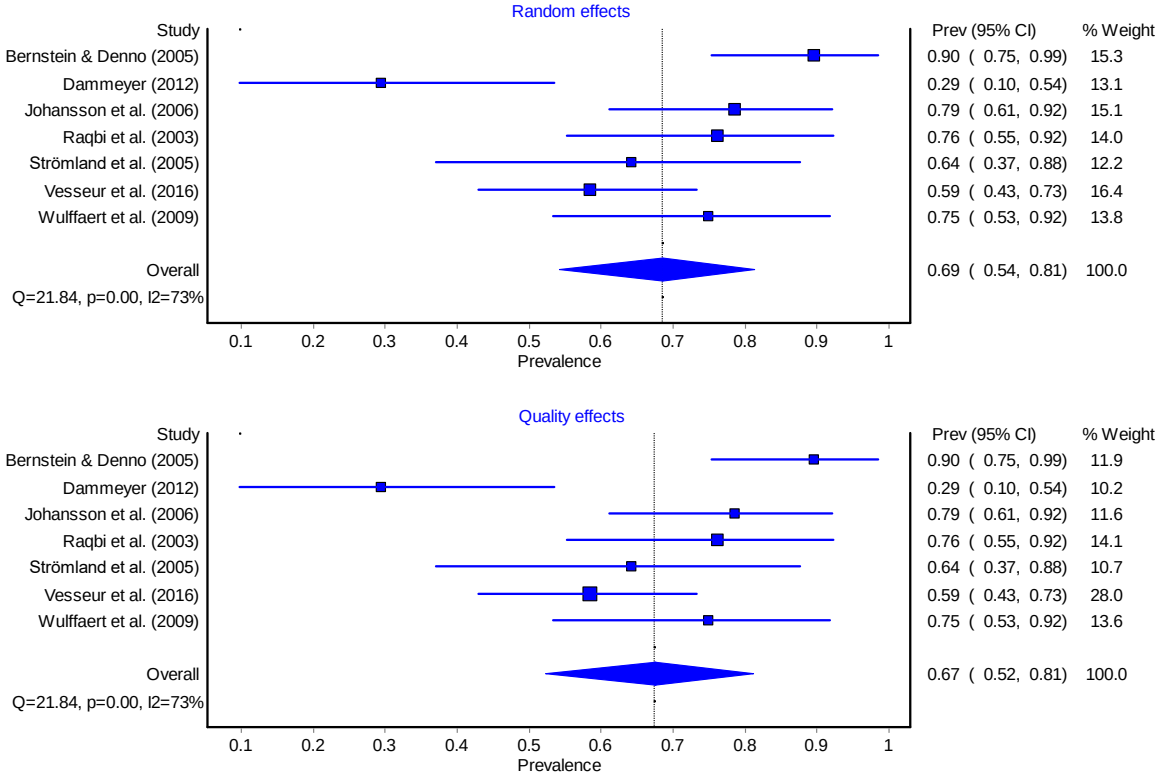

Figure 4 Pooled prevalence estimates of intellectual disability

Language development

Language development was discussed in nine papers. Prevalence of communication deficits was reported in three, indicating 80% to 100% may have substantial communication difficulties (Dammeyer, 2012; Johansson *et al.,* 2006; Vesseur *et al.*, 2016). Four reported on severity of deficits: two estimating them as much as three standard deviations below norms (Santoro *et al.,* 2014; Wulffaert *et al.,* 2009), while Vesseur *et al.* (2016) reported deficits at least one standard deviation below the norm in almost all cases. Dammeyer (2012) found severely delayed language in 18% of people, and moderate delay in 65%. Four articles reported on numbers achieving spoken or sign language. Pooled prevalence estimates suggested 29-47% are likely to achieve spoken language (Table 8; Figure 5). As might be expected, deaf-blindness, hearing loss and cognitive delay were negatively associated with receptive language development (Vervloed *et al.,* 2006; Vesseur *et al.,* 2016).

Features associated with 'ASD:' Social development; repetitive behaviours; sensory issues

Issues relating to autism spectrum conditions including social development, repetitive behaviours, and sensory issues were reported in 18 papers. Eight offered information relating generally to social development and preferences, and 16 described social issues for people with CHARGE with reference to a potential association with features assessed when diagnosing ASD. The possibility of 'ASD' being associated with CHARGE was the most thoroughly investigated topic amongst literature generated in this review.

Two of the eight papers reported on general social development in terms of skill deficits, suggesting most people with CHARGE have a deficit in social development (Table 9). In Santoro *et al.* (2014) the full range of performance quotients ranged from around 5 to 150, where the average is 100, indicating wide variability. For people aged over three years, the median age-equivalent social skills score (~20 months) was substantially lower than median age (~75 months). Two reports highlighted prevalence of deficits with social rules: 38% in Souriau *et al.* (2005); Hudson *et al. (*2016) found 10% broke social rules around mealtimes.

Table 9 Percentage of people with CHARGE reported to have a social skills deficit

Article	N	Quality				Estimate
		SI	CS	AC	GC	
Blake *et al.* (2005)	30					53%
Thelin and Thusner (2005)	28					86%

A theme appeared among five studies that people with CHARGE may present as withdrawn, isolated, and self-absorbed. Souriau *et al.* (2005) concluded 25-60% tend towards social withdrawal; a quarter isolate themselves around adults, and a third around children. In Thelin and Fussner (2005), parents identified their children as lacking in engagement in communication for interpersonal purposes. Wulffaert *et al.* (2009) observed that over 50% were reported as 'aloof and in their own world.' Hartshorne *et al.* (2009) found people scored on average, above 50th percentiles for difficulties with self-absorption and communication disturbance. Finally, Graham *et al.* (2005) found that people with CHARGE were significantly more withdrawn and had less social contact or proclivity to help others relative to people with other genetic syndromes known for higher sociability such as Williams and Down Syndromes.

Table 10 presents observed prevalence of four types of atypical behaviour. Pooled prevalence estimation was not attempted because of inconsistencies in how behaviours were labelled between studies. For example, Bernstein and Denno (2005) report on many behaviours that might otherwise be labelled as motivated by an urge to maintain order or routine but identify all actions in their report as 'repetitive behaviours.' They found 11.2 'repetitive behaviours' per person, with all exhibiting at least one, 72% spending one or more hour per day in such activities, and 48% persevering following attempted redirection. For 72%, such behaviours were found to interfere with social activities and relationships and 83% with daily routines. Prominent behaviours included: doing things in order; eating set foods at set meals; shirt tucked in; objects in their place; schedules followed; things must be empty to be finished; perfectionism; pressing or tight clothing; looking for 90-degree angles; interest in numbers or dates; and perseverative questions.

Higher-quality studies suggested that over 50% of people with CHARGE engage in at least one of the types of behaviours identified. More detail is offered about tactile defensiveness: Hudson *et al.* (2016) found 25% would not mix liquid and solid foods during meals, a feature also found by MacDonald *et al.* (2017). Johansson *et al.* (2006) found unusual interest in auditory stimuli in 14%, oversensitivity to noise in 18%, and unusual interest in sensory stimuli in 36-39%. Souriau *et al.* (2005) observed that substances most cited as difficult had unstable sensory information. Souriau *et al.* (2005) found a positive relationship between the need to put things away and enjoyment of jigsaws. Graham *et al.* (2005), in a study with a particularly well-matched control group, found people with CHARGE scored higher on maintaining order than people with other genetic syndromes.

Table 10 Observed prevalence rate of behaviours associated with ASD

Four articles identified levels of reduced sensitivity to stimuli amongst people with CHARGE (Table 11). Pain insensitivity was a common feature, present in over 50% of the higher-quality samples. Also, Deuce *et al.* (2012) reported that 5% of their sample reported no fear of danger, the only study to report on this characteristic.

Table 11 Observed prevalence rates of reduced reactivity indicators

No fear of danger	5%	Deuce *et al.* (2012)	44				

The possibility that the set of behavioural atypicalities observed in individuals with CHARGE may represent presence of autism spectrum disorder was addressed in 10 articles (Table 12). Research focusing on pre-existing diagnoses offered lower estimates than those looking to directly assess evidence of 'ASD' amongst their sample. Pooled prevalence estimates suggested 10-26% may reliably exceed clinical diagnostic thresholds (Figure 6). In total, up to 60% may present with a behavioural characteristic that could be interpreted as at least weaker evidence of diagnosable ASD, or of sub-clinical ASD. In addition, Hartshorne and Cypher (2004) note that 15 of 25 behaviours associated with ASD were present in at least one-third of their sample.

[1] Estimate from Christensen et al. (2012)

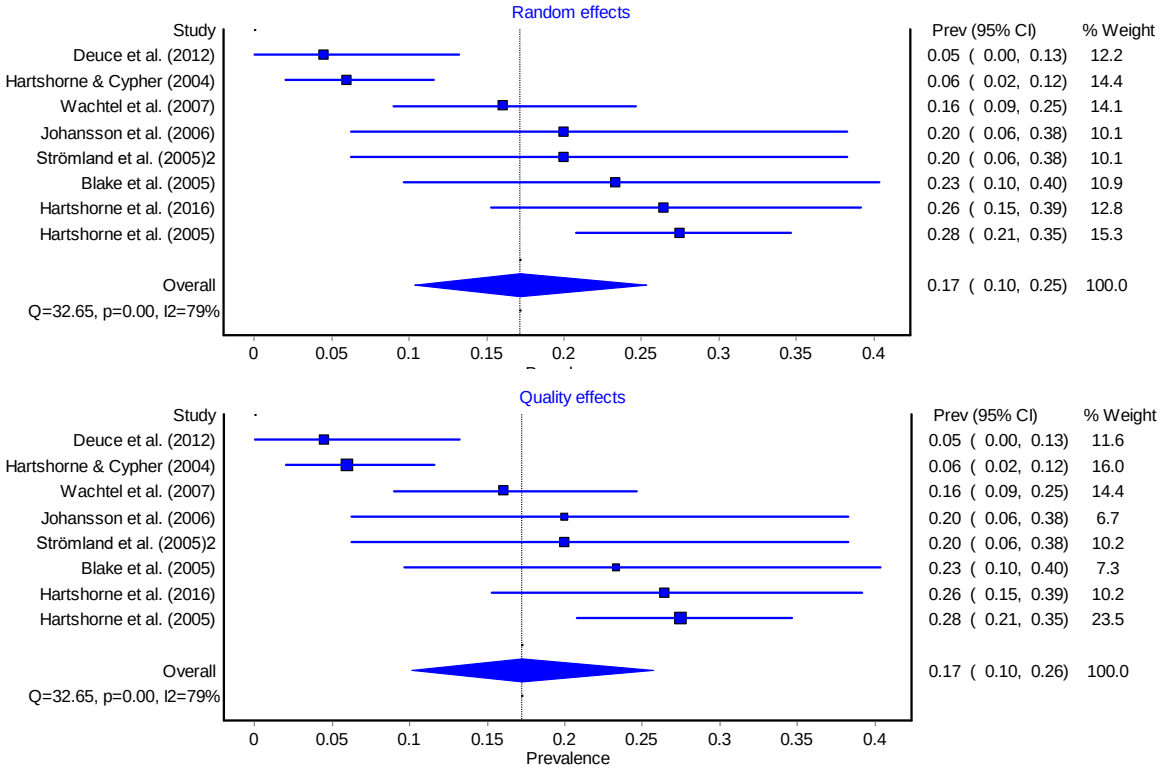

Figure 6 Pooled prevalence estimates for ASD diagnosis

The two reports focusing most exclusively upon ASD-associated features amongst people with CHARGE produced evidence of elevated rates of behaviours indicative of ASD, but not in the same way as in ASD as identified in people with no other neurodevelopmental diagnosis. Hartshorne et al. (2005), using the Autistic Behaviour Checklist measure, found mean scores lower than those typically found in people reaching diagnostic thresholds for ASD and higher than those for deaf-blind people, with most variance for people with CHARGE. This was supported by Graham *et al.* (2005), who found their sample more likely to show behaviour associated with ASD diagnosis, but with lower impairment. Scores were more similar to those of people diagnosed with ASD on items rating social and self-help factors, and it may be on these measures that people with CHARGE most commonly 'tip the scales' of diagnostic assessment tools. Statistically significant relationships found between other features and ASD-associated symptomatology are summarised in Table 13. This may corroborate a position that associated difficulties in people with CHARGE may be more likely to be due to sensory impairments than to ASD as generally defined.

Emotions and features associated with mental health diagnoses

Eighteen articles reported results that may be associated with mental health of people with CHARGE. These are separated here into sleep difficulties, emotional difficulties, psychiatric diagnoses, ADHD and associated symptoms, and harming behaviours.

Seven papers reported on the presence of sleep difficulties (Table 14). Observed prevalence of significant difficulties varied widely, between 14-59%, with pooled prevalence estimates suggesting that between 20-49% experience difficulties with sleep (Figure 7). Only Dammeyer (2012) appeared to account for milder problems, which, added to reports of more substantial trouble, could suggest some level of difficulty in up to 88%, a level not dissimilar to reported difficulties for people with 'pervasive developmental disorders' more generally (Couturier *et al.*, 2005). Hartshorne *et al.* (2009) found sleep difficulties were associated with behavioural difficulties, deaf-blindness, ear infections, and the extent to which parents rated their children as "self-absorbed."

[1]Estimates from Couturier *et al.* (2005)

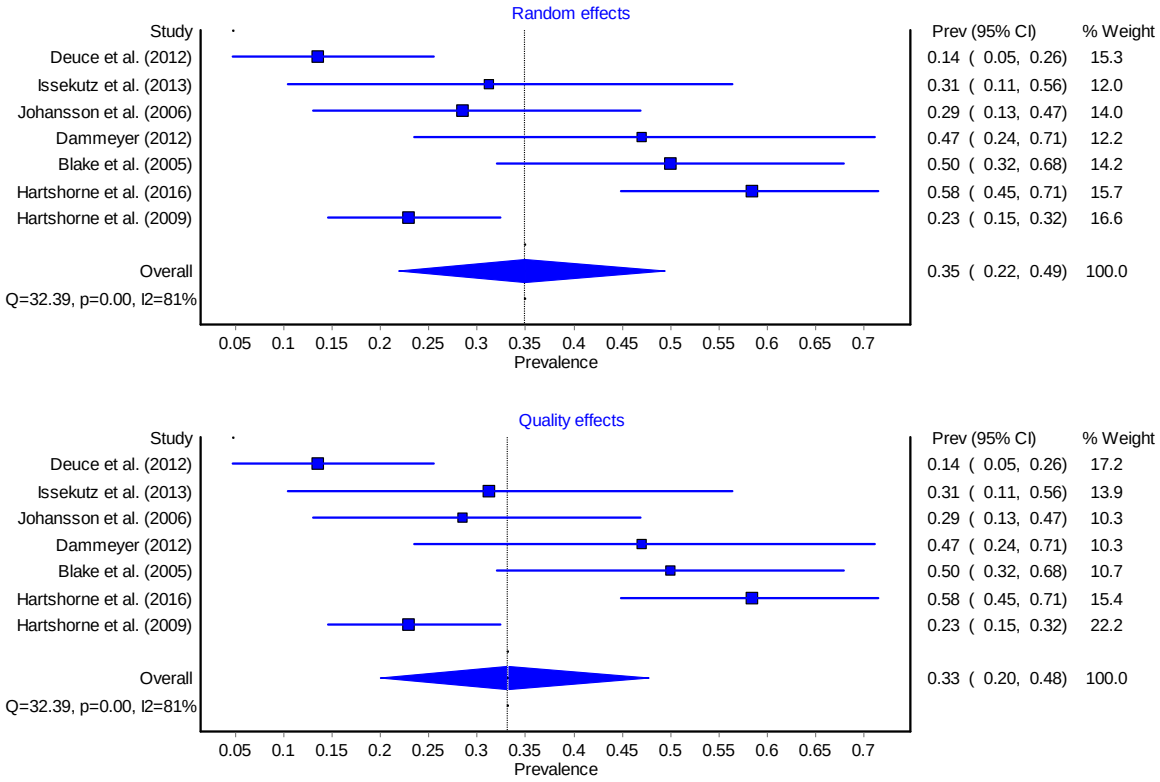

Figure 7 Pooled prevalence estimates for sleep difficulties

Four research papers produced estimates of emotional problems within two common areas of emotional difficulty: anxiety and low mood (Table 15). Pooled prevalence estimates (Figures 8 & 9) suggest elevated levels of both compared with TD people, but lower than rates in ASD diagnosed populations. In addition, Hartshorne *et al.* (2009) found overall mean anxiety and low mood scores within average ranges. Correlations were identified between emotional problems and age (r=.46, p<0.05), number of hospitalisations (r=-.59, p<.001) (Vervloed *et al.,*

2006), and other emotional problems (Souriau *et al.,* 2005). Pooled prevalence estimates were calculated separately for anxiety and low mood estimates; due to the large difference caused by means of data collection, Wachtel *et al.* (2007) data was not included.

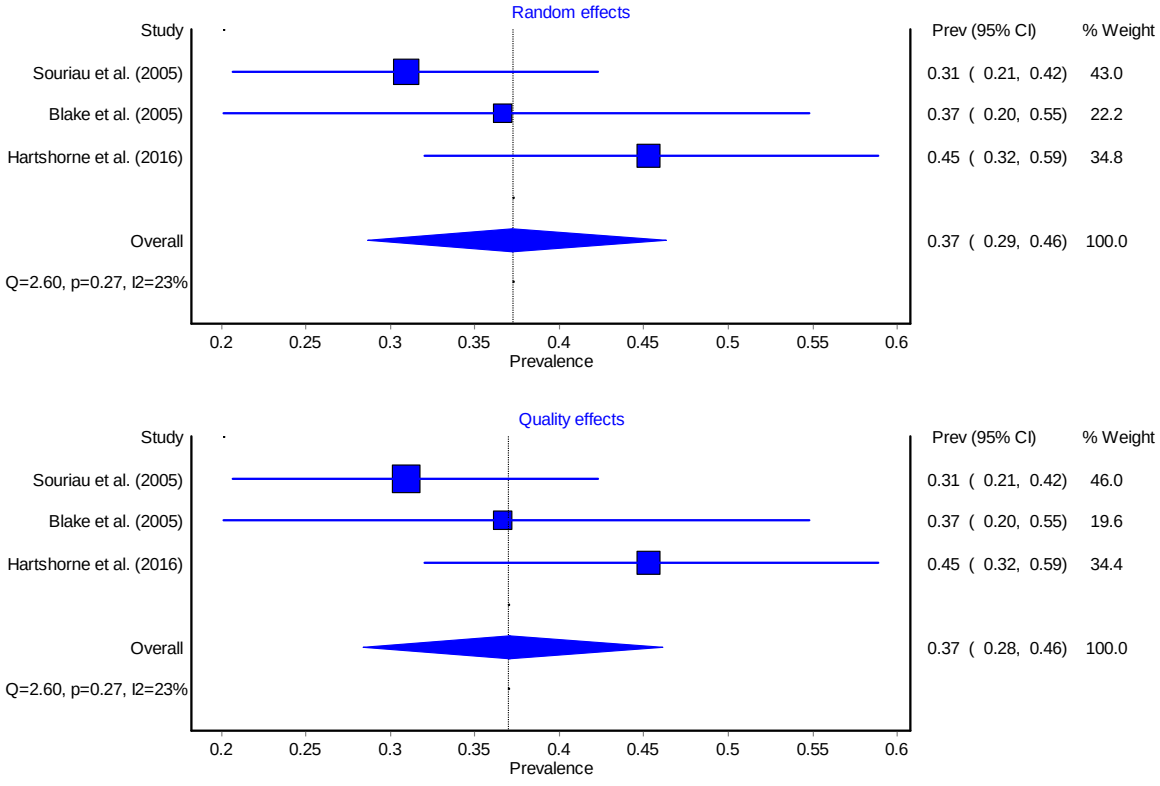

Figure 8 Pooled prevalence estimates for anxiety difficulties

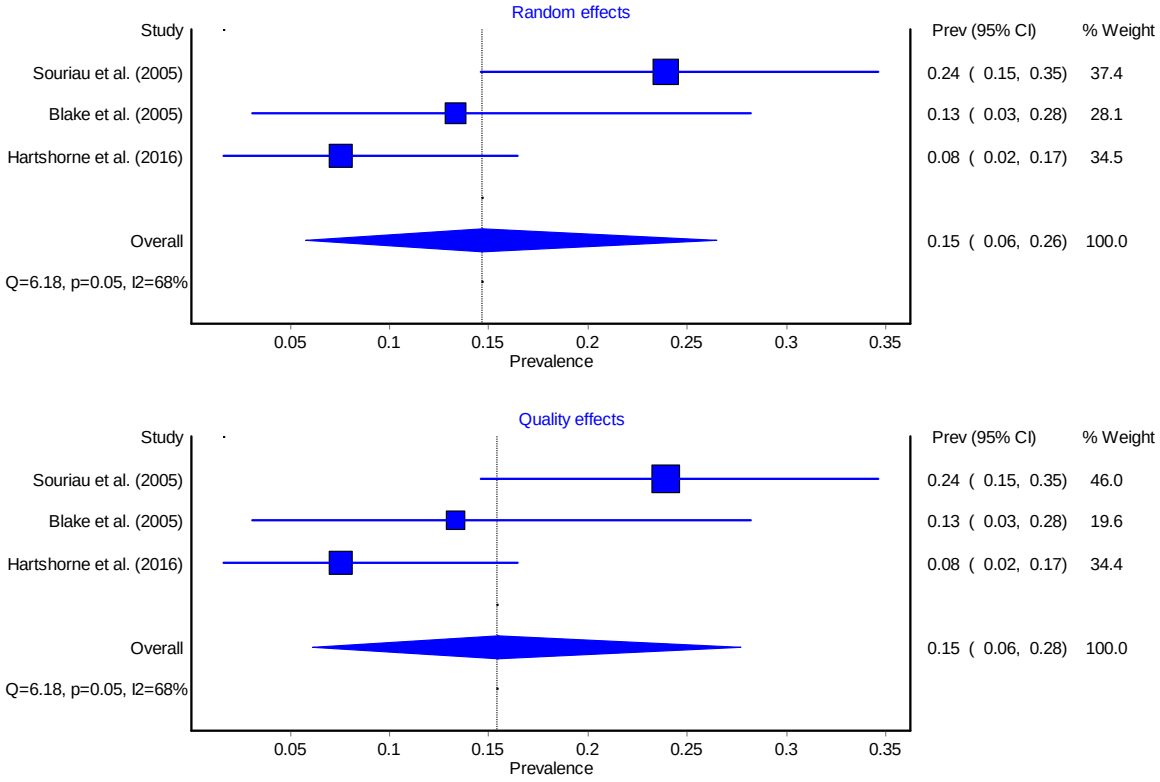

Figure 9 Pooled prevalence estimates for difficulties with low mood

Seven articles reported on the presence of behavioural features that are closely aligned with specific psychiatric diagnostic labels. These are presented in Table 16. For clarity, estimates relating to 'ADHD,' attention, and hyperactivity are presented separately. Where appropriate comparison data were identified, people with CHARGE tended to be identified as struggling with higher numbers of features associated with emotional distress relative to TD people and at levels similar to people with ASD diagnosis. Particularly common issues included obsessive-compulsive problems, and Tourette's syndrome/Tics. Hartshorne & Cypher (2004) also reported that one or more of 13 Obsessive-Compulsive Disorder-associated and one of two tic behaviours occurred in at least one third of their sample. It appeared that research using more formal or professional assessment methods produced higher estimates of diagnosis-consistent behaviour. Added to this list, Graham *et al.* (2005) reported on somatic complaints, finding people with CHARGE had fewer somatic complaints than people with Prader-Willi Syndrome, but equivalent levels to people with Down or Williams Syndrome.

Some significant associations were found: Hartshorne & Cypher (2004) identified a positive correlation between age and obsessive-compulsive problem behaviours (r =.23, p<0.05), and deaf-blind people with CHARGE had a greater number of problematic behaviours across the diagnostic spectrum. Vervloed *et al*. (2006) found that children who spent more time in hospital tended to have fewer 'delinquent behaviours' (r=-.49, p<0.05) and that boys with CHARGE were not at increased risk of delinquency even when appearing frustrated.

Co-occurrence of CHARGE with difficulties in attention were common (Table 17). Pooled prevalence of diagnosed ADHD was estimated at between 6-14%, higher than TD children and lower than children with ASD diagnosis. Observed relevant behaviours were observed in up to 42-77%, and nine or more of ten ADHD behaviours were rated as present in at least 33% of people in Hartshorne and Cypher's (2004) study. Behaviours that may be labelled as representing attention deficits, impatience, and hyperactivity may therefore be commonly observed in people with CHARGE. Additionally, hyperactivity was on average the highest scoring domain for people with CHARGE on the developmental behaviour checklist in Wulffaert *et al*. (2009) and was the most prevalent problem associated with sleep problems in

Trider *et al*. (2012). Owing to the difference between estimates of diagnosed ADHD and reported prevalence of behavioural features associated with the disorder, pooled prevalence estimates were calculated separately for these two groups (Figures 10 and 11).

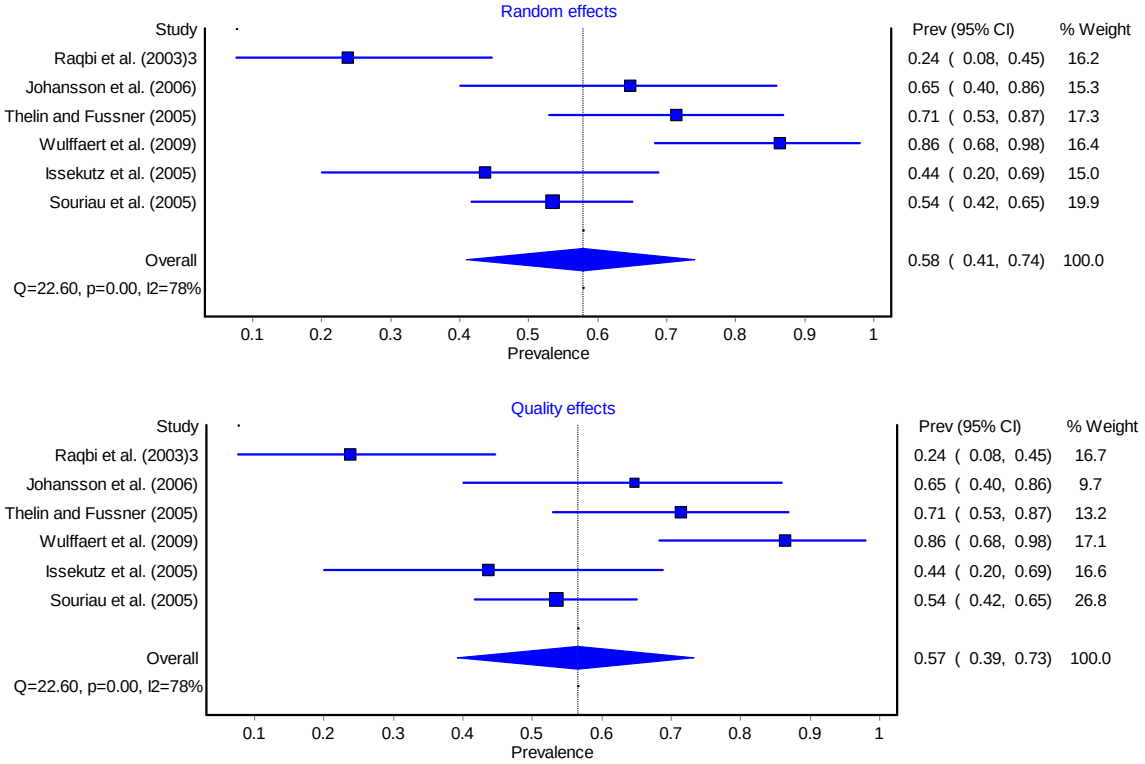

Figure 10 Pooled prevalence estimates for ADHD diagnosis

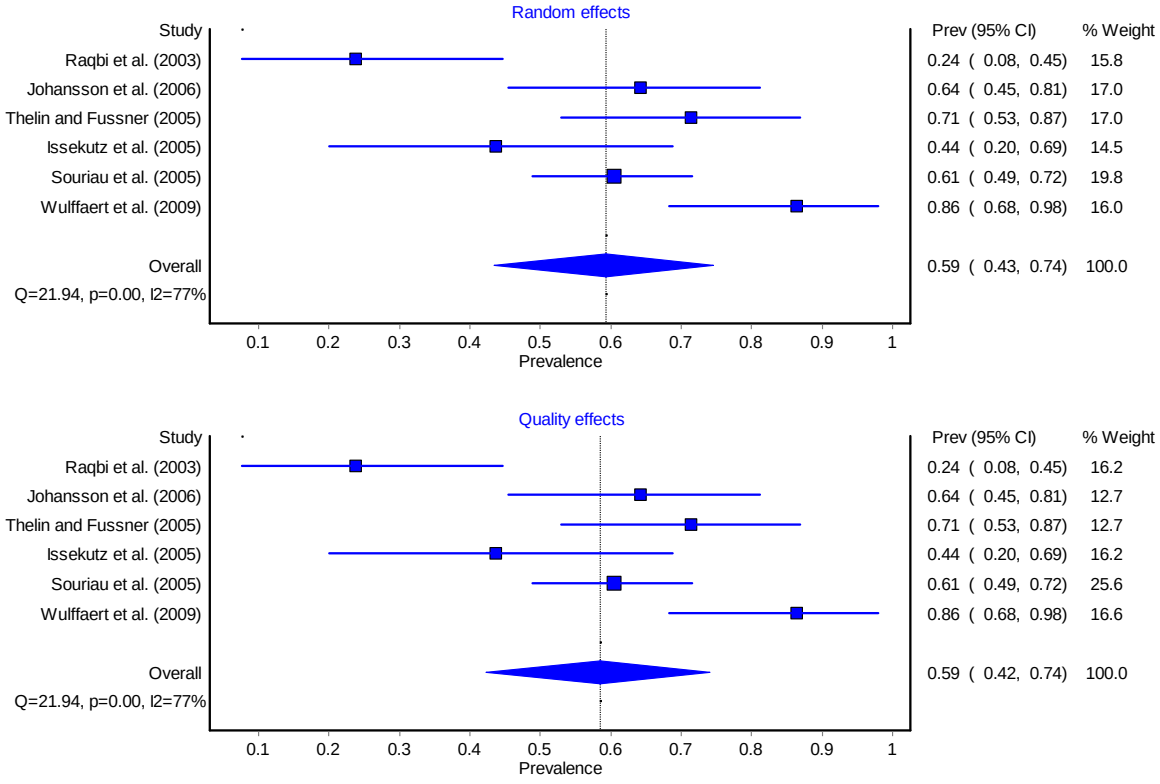

Figure 11 Pooled prevalence estimates for ADHD symptomatology

Five papers reported on the extent to which people with CHARGE were observed to engage in behaviours that could cause injury to themselves or others (Table 18). Estimates of

the prevalence of aggression were consistently reported as substantially higher than for TD people or those with ASD diagnoses. Souriau *et al.* (2005) found significant correlations between aggression to self and aggression to others. Much of the aggressive behaviour may be due to management of the individual; Bernstein and Denno (2005) found that if people with CHARGE were redirected when engaging in repetitive behaviours, 34% responded with self-injurious behaviours or with hitting or kicking at the adult. Hudson *et al*. (2016) added that 15% of people with CHARGE would become angry or aggressive if their plate was taken away from them during feeding. When comparing CHARGE with other syndromes, a pattern was found whereby people with CHARGE appeared equivalent in anxiety and low mood, but more prone to difficulties with anger (Graham *et al.,* 2005; Wulffaert *et al.*, 2009). Pooled prevalence estimates were calculated separately for self-injury and aggression (Figures 12 & 13). Due to the differences caused by means of data collection, results from Wachtel *et al.* (2007) were not included.

Discussion

This review found a total of 33 papers of sufficient quality and relevance to the observed behaviour of people with CHARGE syndrome. Besides levels of concordance with

clinical diagnostic characteristics, the behavioural areas attracting the most attention were features associated with ASD and aspects of maturation and development including language and motor skills. Quality ratings ranged from 0.33 to 0.92 with a median score of 0.50. Only one paper identified employed a random or total population sample (Issekutz *et al.*, 2005), and only two directly compared people with CHARGE to a control group matched on highly-relevant criteria (Graham *et al.*, 2005; Issekutz *et al.*, 2005), such as intellectual ability; most relied upon TD norms.

People with CHARGE appear to vary significantly in their fundamental abilities relative to the average whilst very young, then to diverge markedly from typical development trajectories as their peers advance. In Santoro *et al.* (2014) abilities varied up to 3 years of age; and the oldest participants (up to 33 years-old) had the greatest delays. Reduced functioning three standard deviations below average was found for several basic developmental tasks including achieving motor milestones, adaptive functioning, and language ability. Around one-fifth of people appear to have average-level IQ, while 50-80% potentially have IQs that justify a diagnosis of intellectual disability. Most adolescents and adults achieved independence in basic self-care skills but fewer than half did so for more complex skills such as managing finances. Only 29-47% of people achieved verbal communication, with 21-53% achieving sign language, and 10-39% never achieving symbolic language at all.

Socially, people with CHARGE appear to be at risk of lower ability and tend towards behaving in a withdrawn manner. Difficulties may be particularly apparent around children and groups, and people may benefit from having a single adult supervisor. People with CHARGE appear to be most at risk of emotional difficulties associated with diagnoses of OCD, attention and hyperactivity, anxiety, and sleep difficulties, and to engage in harmful behaviour. People with CHARGE showed consistently elevated prevalence rates for characteristics that are often associated with diagnostic categories of ASD and ADHD. In both cases, actual diagnostic levels fell significantly short of reported behavioural difficulties associated with those conditions. There was some dispute about the possibility that observed

ASD 'traits' may be caused by a 'primary' ASD condition, with sensory difficulties also posited to have strong explanatory potential (Graham *et al.*, 2005; Hartshorne *et al.*, 2005; Hartshorne & Cypher, 2004). As ASD may be argued to itself represent a heterogeneous social construction with evidence of a biological basis showing limited reliability (e.g. Runswick-Cole *et al.*, 2016), it is perhaps unsurprising that the literature presents an unclear picture.

Unsurprisingly, a complex picture of interrelationships emerged that makes it difficult to make strong assertions as to causal relationships between behavioural features. Some features were repeatedly associated with difficulties in other areas. For example: age of walking was associated with adaptive functioning; deaf-blindness with adaptive functioning and developmental delay, language form and delay, poorer executive functioning, social ability, sleep problems, 'ASD' features, and a greater number of problematic behaviours; ASD-associated features were positively correlated with prevalence of self-injury, hyperactivity, medical conditions, and problematic behaviours. Mental health difficulties also tended to be associated with greater numbers of problematic behaviours. Where aggression occurred, it seemed to relate to frustration at preferred behaviours being disrupted by others. Primary difficulties with ability appeared to be exacerbated by interactive processes resulting in low confidence and relationship difficulties. Perhaps owing to this difficulty in clarifying causality, clinical diagnoses of, for example, ASD, ADHD, and mental health difficulties, appeared to be rarer than prevalence estimates obtained in more direct research, perhaps reflecting the wider issue of diagnostic overshadowing (Mason & Scior, 2004).

Difficulties identifying causation in these research papers are exacerbated by frequent lack of clarity in how CHARGE diagnoses were confirmed, plus relatively rare adoption of well-matched comparison or control groups. The latter factor makes it difficult to identify putative differences between people with CHARGE and people with deaf-blindness caused by other factors, or between people with CHARGE and other genetic syndromes causing intellectual or physical disability. In addition, where relationships were reported between behavioural factors, this was often done in the absence of the data for each factor. For example, two

papers (Hartshorne et al, 2005; Wachtel *et al.* 2007) reported correlations between age of walking and other factors without reporting the mean age of walking observed. Whilst many papers fared better on the quality criterion of assessment of symptoms, still many relied upon the reports of parents and carers for symptom report, relatively few involved direct consultations with medical consultants and even where papers reported diagnoses, it was often difficult to determine whether the children were diagnosed and with what specific diagnosis (e.g. Wachtel *et al.*, 2007). Much of the evidence reported here may therefore be seen more as a description of how people with CHARGE are experienced by those around them, than a cataloguing of verified characteristics.

As expected, these problems raise issues with the possibility of achieving a clearly delineable behavioural phenotype for CHARGE. The variability of physical and behavioural characteristics observed in people with CHARGE is a problem added to by the lack of consensus in the research about how behaviours and syndromes are reported, such as whether clinically diagnosed cases are included alongside genetically-verified diagnoses. Several reports did focus exclusively on genetically-verified cases and researchers appeared to be increasingly reporting upon numbers of genetic diagnoses and focusing on genetic cases (e.g. Husu *et al.,* 2013; Santoro *et al.,* 2014). Bernstein and Denno's (2005) use of 'repetitive behaviour' as a term to summarise a range of behaviour features, although typical of intellectual disabilities literature, differed from other studies here and blurred the distinctions between, for example, 'repetitive behaviour' and 'stereotypic movements.' Although behavioural trends were identified, observed prevalence rates for most features were below 50%, and as such any individual diagnosed is less likely than not to experience each behaviour. Finally, regarding behavioural phenotype research, it is notable that every single behavioural feature mentioned is considered in terms of deficit; no piece of research used here offered any single examples of positive ways in which people with CHARGE may be experienced, which may conceivably lead to an argument that behavioural phenotypes could further stigmatise an already disadvantaged group.

Following the results of this review, diagnosticians may be aided by an awareness of how certain features may appear to represent one type of difficulty (ASD-associated characteristics), but may actually be a consequence of another, such as deaf-blindness. Arguably, this should not dissuade attempts at reaching functional diagnoses for individuals and their families, as an under-diagnosis of relevant problems could lead to under-resourcing of support for those in need. As the research is not at this stage able to help clarify what features may be caused by which factors, intervention and support plans may need to be applied holistically and scientifically. Clinicians should not, for example, be discouraged by failure of an intervention focused on features associated with ASD diagnosis to reduce self-destructive behaviours, and instead consider other features of an individual's presentation as potentially relevant. Policymakers, likewise, should recognise the complexity that is intrinsic in treating people affected by CHARGE and offer appropriately flexible support. Researchers would benefit the increasing knowledge base around people with CHARGE by developing a clear and consistent shared language. This is a particular problem in CHARGE due to the variety of presentation. There are, for example, several apparently outdated terms, such as 'Hall-Hittner Syndrome' and 'CHARGE Association,' associated with the condition still in use and these do not seem to consistently represent the condition since a meaningful genetic marker was discovered. Likewise, symptom-specific measures continue to vary widely in their use and consensus, limiting the potential for focused meta-analysis.

This project benefited from a broad search strategy that allowed for many relevant research papers pertaining to behavioural features in CHARGE to be recognised. This has its drawbacks however, as a high volume of irrelevant papers was generated and therefore many quite stringent inclusion and exclusion criteria were required, potentially reducing replicability. This difficulty may also reinforce the stated need for authors to be consistent in terminology. Quality appraisal helped determine which papers were more valid and reliable, however it did not account for the relevance of information contained. Hudson *et al.* (2016), for example, produced highly-relevant data but scored lower because of reliance upon self-completion

methods and a limited control group. Some nuance may have been lost by giving equivalent weighting to each of the four factors. A further difficulty was that due to the variety of papers reporting on the topic, drawn from a variety of research strands and from groups that varied on, for example, means of diagnosis or age, for many papers data relevant to this topic was reported with little depth or context and it is therefore possible that in synthesis some data may have been inaccurately or simplistically compared.

Future research should, in addition to following the guidelines set out above, aim to aid in the delineation of causality with regards to behavioural features. This would enable diagnosticians and clinicians to identify which aspects of a person's presentation are associated with which others, and to anticipate problems that may develop in future. One way of achieving this would be to focus on producing longitudinal research with meaningful comparison groups. In particular, it is important to draw clear comparisons, using consistent assessment methods, between people with CHARGE and people with other genetic conditions, deaf-blindness, or ASD diagnosis.

To conclude, CHARGE is a highly variable genetic condition that results in a range of physical, sensory, and behavioural issues. This heterogeneity creates difficulties for the applicability of the behavioural phenotype model, as it is difficult to identify a clear set of behavioural features for the condition, or to infer causation with much accuracy owing to the interrelatedness of individual features. Nonetheless, this project has offered some possible insight into the types of behavioural tendencies that have been discussed in the literature since the condition was recognised in 1979. With some more consistency in the approaches of future research endeavours, it may be possible to assert more clearly which behavioural features may be associated with CHARGE itself, and which may be due to the other interlacing problems faced by those with the condition and their families.

Part B: Empirical Report

How does the different facial morphology of children with a range of genetic neurodevelopmental syndromes affect how they are perceived by others?

Abstract

How does the different facial morphology of children with a range of genetic neurodevelopmental syndromes affect how they are perceived by others?

Craig Griffiths

People with intellectual disabilities are understood to be particularly vulnerable to problems of social exclusion, stereotyping, and negative social attitudes. Research has suggested that one factor influencing social judgments is facial appearance. Genetic neurodevelopmental synstomes are conditions understood to result from mutative alterations in DNA structure affecting many aspects of functioning. Examples include Down syndrome, Williams syndrome, Angelman syndrome, Prader-Willi syndrome, Fragile-X syndrome, Cornelia de Lange syndrome, and Smith-Magenis syndrome. Each of these GNSs is associated with a dysmorphic facial phenotype, such that people with the condition share facial similarities that would not typically be seen in people without that diagnosis. Autism spectrum disorder (ASD) is a behaviourally defined diagnostic category that has not been associated with a genetic causality, but which some researchers have associated with a different facial profile. This project aimed to identify whether and in what ways the facial morphology of children with a GNS or ASD diagnosis influences trait judgments. Fifty-eight undergraduate students were shown merged face images representing GNS groups at age 12 and ASD diagnosed children at age 9 and asked to make trait ratings whilst an eye-tracker recorded their viewing behaviour. Results suggested significant differences between trait judgments made between each face and a typically developing, age-matched control image. All images representing people with a GNS were rated as less approachable, attractive, intelligent, and trustworthy than matched control images representing typically developing people. Eye-tracker results suggested differences in how participants looked at GNS face images compared with TD face images, with no difference for ASD diagnosed face images. Observations relevant to the clinical and social treatment of people with GNSs are discussed, as are implications for future research into face-based trait judgments.

Introduction

Social attitudes and people with intellectual disabilities

People with intellectual disabilities (ID) in the UK suffer particularly from problems of social exclusion (Cummins & Lau, 2003). Social inclusion/exclusion describes the extent to which particular people have no recognition, voice, or stake in society, and exclusion may result from a range of factors including employment, education, health, and race (Charity Commission, 2001). Major policy bodies have stressed the need to promote greater inclusion for people with ID (House of Lords, 2008; United Nations, 2006). Social attitudes and stereotyping are linked with social inclusion (Nicholson & Cooper, 2013) and are known to be a problem faced by this group (Ditchman *et al.*, 2013, Staniland, 2011). In a recent review, Pelleboer-Gunnink *et al.* (2017) identified that even amongst health professionals, people with ID can be perceived stereotypically as, for example, potentially aggressive, intimidating, uncooperative, child-like and unpredictable.

Social judgments and facial morphology

One factor that research suggests exerts a demonstrable impact upon social attitudes is facial morphology, the form or structure of the human face. People readily infer personality and social traits from faces alone with remarkable consistency. Ratings of specific faces are often remarkably consistent, with minimal differences found between adult raters and children as young as five years-old (Cogsdill *et al.*, 2014). Certain facial features, such as eye size, mouth shape, and jawline, have been shown to reliably influence a distinct range of trait judgments such that face images can be manipulated so that they will elicit desired character ratings (Oosterhof & Todorov, 2008; Sutherland *et al.*, 2013; Vernon *et al.*, 2014).

The real-world validity of face-based social judgments is a subject of controversy amongst researchers. Some studies have found evidence of correlation between face-based judgments and the actual personal or behavioural disposition of the person subject to evaluation (e.g. Enea-Drapeau *et al.*, 2012) whilst others find no such relationship (e.g.

Efferson & Vogt, 2013; Penton-Voak *et al.*, 2006). A possible association between face-based judgments and actual personality could be explained in a number of ways, representing the multiple influences on development. For instance, a certain amount of influence may be due to underlying genetic factors that are predictive both of facial morphology and behaviour (Sallis *et al.*, 2018). In addition, *prima-facie* judgments could interact with behaviour development through social interactions, confirmation bias (Sherman *et al*., 2012), and 'indirect effects' (Hodapp, 1997; 1999), leading to self-fulfilling prophecies in which originally invalid inferences later become valid (Jussim & Harber, 2005; Snyder *et al.*, 1977).

Early research in the area of facial trait inferences focused primarily upon ratings of attractiveness, finding evidence for a 'halo effect' in which physical attractiveness was associated with positive personal traits (Miller 1970). More recent research has attempted to combine the many possible ratings that any individual might make of a person into a set of reliable ratings made consistently between different faces and multiple observers. In this way, Oosterhof and Todorov (2008) produced a dyadic model including 'trustworthiness,' associated with approachability and emotional expression, and 'dominance,' signaling physical strength. Sutherland *et al*. (2013) expanded upon this, finding evidence for an additional factor of 'youthful-attractiveness' in their model. Some ratings that had previously been suggested as being readily inferred from faces showed stronger loading onto these categories than others; with 'baby-facedness' and 'intelligence' each loading lower than 0.5 onto any one factor. In reaching for reliability, these models may therefore lose some of the nuance of facial trait inferences. In addition to this, there is evidence that trait inferences may be based on an interaction between facial structure and facial expression, and that this is complicated by the observations firstly that certain facial gestalts may themselves resemble emotional expressions (Said *et al.*, 2009) and secondly that perceived intensity of emotional expression increases with certain facial structures (Oosterhof & Todorov, 2009).

Face-based trait inferences may have a substantial impact upon the lived experiences of people in the real world. Langlois (1995) found evidence that the attractiveness of infants

correlated with maternal attitudes and behaviours, suggesting that people's relationships may be affected from birth. Hassin and Trope (2000) showed that trait judgments based on appearance change how verbal information about a person is understood, and influence subsequent decision-making. Todorov *et al.* (2005) found evidence that the success of candidates in real-world elections could be predicted based on inferences of competence made from faces alone, and other research has suggested that leaders may be identifiable by their facial features alone (Olivola *et al.*, 2014). Also, more baby-faced people are less likely to be convicted if charged with intentional crimes, but more likely if charged with negligence (Montepare & Zebrowitz, 1998). In the modern world of social media, where a still image of a person's face may be the only representation of them available during social contact, understanding the influence of facial appearance is of increasing importance (Vernon *et al.*, 2014).

The faces of typically developing (TD) people tend to vary within a consistent range subject to factors of, for example, age, sex, and 'race.' As such, faces may be considered to be more or less average. Research looking at the facial trait inferences has thus far focused exclusively upon how judgments are made of such TD faces. Faces can, of course, vary outside of typical ranges and this has been associated with a range of personal and interpersonal challenges. Examples of facial differences associated with adverse social experiences include orofacial clefting (Tobiasen, 1987), disfigurement owing to accident or disease (Bonanno & Esmaeli, 2012), or facial paralysis (Bogart *et al.*, 2014). The impact of living with facial differences are largely understood to be negative, and can commonly include experiences such as being stared at, feeling left out, teasing, and even physical violence (Strauss *et al*., 2007).

Genetic neurodevelopmental syndromes

Genetic neurodevelopmental syndromes (GNSs) are conditions thought to be the product of mutative alterations in a person's DNA structure affecting numerous aspects of

functioning including neurodevelopment. Certain GNSs are considered to be associated with specific sets of intellectual, physical, personal, and social characteristics that differ from what would commonly be observed in TD people or people with ID due to other causes. These patterns of differences are collectively referred to as phenotypes. Five of the most frequently researched GNSs are Down syndrome (DS), Williams syndrome (WS), Angelman syndrome (AS), Prader-Willi syndrome (PWS), and Fragile-X syndrome (FXS) (Di Nuovo & Buono, 2011), with a number of further genetic syndromes, such as Cornelia de Lange syndrome (CdLS) and Smith-Magenis syndrome (SMS) also receiving increased research attention (REFS). Increasingly sophisticated genetic testing is also leading to an increasing number of identified genetic syndromes.

Whist GNSs may be associated with specific behavioural and psychological corollaries, they are defined primarily by their genetic underpinning or a set of clinical characteristics recognised and categorised by clinical geneticists and related medical professions. DS, for example, is now known to be caused by trisomy of chromosome 21. This contrasts with diagnoses such as 'autism spectrum disorder' (ASD), which is a behaviourally-defined and behaviourally-diagnosed category. Although there is evidence that some genetic factors may correlate with the set of characteristics associated with the ASD label, and many candidate genes are suspected (Yoo, 2015), a single gene cause is generally not found. Numerous hypotheses exist for a biological aetiology of ASD, such as the disrupted connectivity hypothesis (Belmonte *et al.*, 2004), or the theory that ASD may be underlain by autoimmune processes (Ashwood & Van de Water, 2004). One influential theory hypothesises that the condition may be associated with development of an 'extreme male brain' involving increased presence of fetal testosterone (Baron-Cohen, 2002; Baron-Cohen *et al.*, 2011). As with the genetic aetiology hypothesis, evidence supporting these other theories is limited, and therefore, although diagnostic categories exist, it would be inaccurate within the present state of evidence to imply equivalence between categories of GNSs and ASD (Timimi & McCable, 2016).

Many GNSs are associated with a dysmorphic facial phenotype. For example, DS is associated with a facial profile that includes a small nose and mouth, a flat nasal bridge, and eyes that slant upwards and outwards (NHS Choices, 2015) whilst the faces of people with CdLS tend to feature confluent, high-arched eyebrows, thin lips, a small nose, long eye-lashes, and a small jaw (Clark *et al.*, 2012). Despite attempts to position ASD as a neurodevelopmental condition, it is not typically thought to be associated with a divergent facial profile, although some research suggests that there may be atypicalities including facial asymmetry, possibly due to uneven neurological development (Hammond *et al*., 2008). Hypermasculinity in facial morphology has also been associated positively with ASD symptomatology (Tan *et al*., 2017).

GNSs are theorised to contribute to the development of particular behavioural patterns. The notion of behavioural phenotypes was introduced by Nyhan (1972) and behavioural phenotypes have become a focus of increasing interest in GNS research as genetic technology improves (Dykens & Rosner, 1999). A behavioural phenotype might include motor, cognitive, linguistic, social, or psychiatric features (Flint & Yule, 1994), which occur more in one syndrome than in others (Dykens & Hodapp, 2001). DS, for example, has been associated with: relatively strong expressive communication; lowered motivation in challenging activities; aggression and disruptive behaviour; and affectionate and outgoing social behaviour (Daunhauer & Fidler, 2011; Fidler *et al.*, 2008; Visootsak & Sherman, 2007). ASD has traditionally been defined by impairments in social communication and imagination, alongside repetitive behaviours or restrictive interests (Wing's 'triad of impairments;' Wing & Gould, 1979). Diagnostic criteria have developed over time and DSM-5 now defines ASD in terms of a dyad (American Psychiatric Association, 2013): ASD is currently characterized as consisting of social and communication impairments plus repetitive behaviours or restrictive interests, and sensory sensitivity, obsessions, a need for routine, and difficulty in social situations (The National Autistic Society, 2017), as well as a greater predisposition towards 'systemising' over empathising skills (Baron-Cohen, 2002).

Behavioural phenotypes and facial appearance

People's behaviour is generally accepted to arise and develop via interaction with the environment (e.g. Fidler *et al.*, 2008). Differences in behaviour between groups of people may, as implied by behavioural phenotype research, reflect differences at the level of neurophysiological development. Differences in behaviour may also arise via differences in the environment, and thus the behavioural phenotype model is, implicitly or explicitly, based on the presupposition that people in these groups receive the same treatment in the same environments. If, however, people are subject to systematic biases in their social interactions as a result of their appearance, as indicated by trait judgment research, then this assumption may be violated. Just how the environment might differ systematically for people with GNSs has received little research attention.

Since the differences in facial appearance in people with a GNS are relatively consistent (to the extent that geneticists often make hypotheses about the presence of a GNS based on facial morphology) and often pronounced, it is possible that people may make reliably divergent trait inferences about the face profiles of affected people. This is a largely untested hypothesis. If it is the case, then implications may be profound, since judgments may then impact upon the quality of social interactions and behavioural development as well as the judgments of behavioura contributing to the characterisation of behavioural phenotypes. Fidler and Hodapp (1999) found evidence that the youthful craniofacial appearance of people with DS was associated with a perception of 'baby-facedness' and propensity to behave in an immature manner. Assessing the trait judgments made of people with disability is difficult, however, owing to the possibility that people may recognise the presence of a syndrome and make inferences corresponding to known clinical features of the disease, or according to social desirability effects (Enea-Drapeau *et al.*, 2012; Verhulst & Lodge, 2013; Wilson & Scior, 2014). It may be possible to circumvent such effects by not informing people about the presence of GNSs. As very few GNSs share the social status of DS, people may be less likely to identify the presence of a syndrome just from viewing face images out of any wider context.

Facial processing

With advances in technology, researchers are able to explore the ways that different faces are 'read' by observers in ever more nuanced ways. Research using eye-tracking equipment suggests that, at least in the 'West,' faces are processed in a distinctive T-like pattern that involves emphasis on the internal features of the eyes, the nose, and the mouth, particularly the eyes (Janik *et al.*, 1978; Walker-Smith *et al.*, 1977; Peterson & Eckstein, 2012). This is important as people who tend to focus their attention on internal features of the face are better able to accurately identify expression than those who look at distal features (Rennels & Cummings, 2013). Systematic differences in how people explore faces have been shown to be influenced by culture and social attitudes, and may provide an implicit measure of prejudice (Blais *et al.*, 2008; Hansen *et al.*, 2015). There are indications that people tend to dwell disproportionately on areas of marked facial difference when looking at atypical faces (Hills & Pake, 2013; Madera & Hebl, 2012; van Schjindel et al., 2015). Unbalanced attention paid to aspects of facial difference may emphasise or exaggerate those differences in the eyes of the observer, leading to a greater perception of difference that could exaggerate trait inferences and social consequences for the individual.

Technology has not only improved the reliability with which it is possible to observe how a person looking at a face behaves in response to visual stimuli, but has also enabled ever-greater means of standardizing the images themselves. The potential to 'merge' a collection of face images together to make a single image that represents an average of constituent images has advanced quickly in recent years. It has become possible for anybody to produce such images via open access online tools such as facesearch.org (DeBruine & Jones, 2017), and more complex tools are available for interested researchers (e.g. InterFace; Kramer *et al.*, 2017). Proponents of the technology have advocated its utility as a means for making clinical diagnoses of conditions associated with a reliable facial phenotype. In several articles, Professor Peter Hammond (see, e.g. Hammond & Suttie, 2012), has produced sets of three-dimensional face models for a range of GNSs, and has shown that it may be possible to

diagnose genetic conditions based on face shape alone using these methods. This work has produced a set of high-quality merged images of people with these conditions that make it possible to explore how the facial phenotypes of these conditions might affect facial processing.

Research suggests that people reliably 'read' the faces of other people in similar ways. They tend to follow a familiar pattern in how they look at faces, and make potentially invalid but influential trait inferences about people based on what they see. It is not clear to what extent these processes remain true when people view the faces of people with GNSs with phenotypical facial dysmorphology. If people respond to the faces of people with a GNS in reliably different ways then this could have consequences for the development and social inclusion of affected persons. Although it has no known consistent genetic or biological aetiology (Timimi & McCabe, 2016), ASD is a diagnostic label purported to represent a more-or-less reliable behavioural presentation and has been associated with a facial profile that differs from people without the condition (Aldridge *et al.*, 2011). It is possible that people might interact with people with ASD diagnoses differently where any dysmorphology exists, and this too requires clarification. It may also be the case that top-down processes, such as knowledge that a person has a diagnosis of a genetic condition, influences trait judgments.

This project aims to identify whether and in what ways the facial morphology in children with a GNS or ASD diagnosis influence how they are perceived by others relative to children with typical facial morphology. Specifically, whether their faces are 'read' differently, with more attention paid to differences in facial morphology, and whether they are judged differently according to social trait dimensions. It also aims to identify whether knowledge that the faces belong to people with genetic neurodevelopmental syndromes significantly affects either of these factors.

Research questions

1. Are there differences in trait judgments made of face images representative of people with a GNS or ASD diagnosis and face images representative of those with typical development?

2. Are there differences in the attention paid to facial features when looking at face images representative of people with a GNS or ASD diagnoisis and face images representative of those with typical development?

3. Are there differences in the total number of fixations made when looking at face images representative of people with a GNS or ASD diagnosis and face images representative of those with typical development?

4. Are there differences in the trait judgments made depending upon whether participants are informed about the presence of images representing people with a GNS or ASD diagnosis?

5. Are there differences in the time it takes to make a trait judgment for faces representative of a GNS or ASD diagnosis and faces representative of those with typical development?

6. Are there differences in how much impact informing participants about the presence of images representing people with GNSs has on social judgments depending on which face image is being looked at?

Method

Participants

Participants were 58 undergraduate students who completed the research in exchange for course credit as part of the Experimental Participation Requirement at the University of Leicester. All 58 contributed data to the judgment rating procedure, 48 to the eye-tracking procedure.[3] In the judgment rating procedure there were 28 in the informed

[3] Eye-tracking data for 10 participants were removed due to concerns regarding the preservation of equal conditions amongst all participants that resulted from methodological inconsistency between these participants. These 10 had lower lighting levels than the remaining 48, which affected data quality.

condition, 30 in the uninformed condition. In the eye-tracking procedure, participants were split equally between the information conditions. Although nobody declined to participate in the research, seven participants could not be satisfactorily set up in the eye-tracking machine and so data collection was not completed.[4] Such problems with calibration are common in eye-tracking research and have been discussed elsewhere (e.g. Vadillo *et al.*, 2015). All participants had normal or corrected-to-normal vision and confirmed that they could clearly see the stimuli before proceeding. Participant demographics information can be found in Appendix H. Sample size was informed by a power calculation based on two pilot studies (unpublished).

Apparatus and stimuli

The experiment was conducted using the Eyelink 1000 system for Windows Version 4.594 (SR Research Ltd.). The research programme was created using SR Experiment Builder and displayed on a flat-screen monitor (21" CRT monitor; screen resolution 1024 x 768 pixels; 85hz), the top of which was positioned 745mm from the fixed chin and forehead rest, the bottom 770mm. Participant eye level was 3/4 of the distance up the screen. Participants interacted with the programme using a standard mouse in their dominant hand. They sat in an office chair that could be adjusted for their comfort.

Stimuli consisted of seventeen images obtained from Professor Peter Hammond (Appendix I). These were three-dimensional models of face shape averages created by using laser and photogrammetric devices to capture meshes of points on individual human faces and averaging them together to produce a face model composite which represents the contributing faces. This technique was applied by Hammond (see, e.g. Hammond & Suttie 2012) to age-matched children with a range of GNSs and also TD children to produce face model averages that may be said to represent those groups at those ages. There were eight

[4] In almost all cases, difficulties with calibration was due to reliance upon visual aids that distorted the eye image.

twelve-year-old GNS images representing AS, CdLS, DS, FXS, PWS, SMS, and WS. All GNS images were 'sex-neutral,' having been produced from a mixture of images from males and females. Two twelve-year-old TD images served as controls, one showing an average of female faces and the other of male faces, each developed in the same way as the GNS images. For all comparisons, the data for the TD male and female faces were averaged together to produce a set of single, combined control scores. Two further images were used: one male diagnosed with ASD (age standardised to nine) plus an age- matched TD control. The remaining six images served as distractors, showing TD face compositions for males and females at ages eight, sixteen, and twenty, and were included to reduce the ratio of images that might more clearly suggest GNSs in the hope that this would reduce the likelihood that uninformed participants might intuit that manipulation.

Images were standardised (using paint.net 4.0.16) to reduce the possibility that irregularities would distract from facial morphology. Image height was standardised to 500 pixels (13cm) with no gap between the edge of the face and the edge of the whole image. To preserve facial proportions, images therefore varied in width. Image 'noise' pixels (random light or dark pixels that stood out from surrounding pixels) left over from the averaging process were removed to produce an even texture. Pupils were altered in density and size to produce clearly defined pupils pointing forwards with corneal light reflections shown in both eyes. Images were also blurred slightly to reduce pixilation at the edges. All images were presented in greyscale upon a solid black background. All faces had ears removed due to low image quality on the ears of many of the faces. Foreheads were cropped above the eyes using a black arc shape standardised at four points, one at either end and two at equal intervals within the line. The points at either end of the line were positioned 64 pixels below the top of the image at either end of the face and the two points within were then set 7 pixels from the top of the image.

A unique set of interest areas (IAs) was created, each individually made so as to correspond to each face type and account for the variability in positioning of facial features

between faces (Appendix I). These were for each eye, the nose, and the mouth, reflecting precedent in the literature (e.g. Hessels *et al.*, 2016). Attempts were made initially to use the limited-radius Voronoi-tessellation method (Hessels *et al.*, 2016) to construct IAs, however, variation in the size of individual features for certain faces meant that the resulting interest areas did not cover all possible fixations on some areas. Eye and nose IAs were all circles 150 pixels in diameter, centred on the pupil and the tip of the nose. All left eye and right eye fixation counts, percentages, dwell counts, dwell percentages, were combined to produce a set of single, combined eye scores. Mouth IAs differed in size and shape to fit each image. To achieve this, an ellipsis was drawn centrally with the top touching but not overlapping the bottom end of the nose IA. Then, the sides were dragged to cover either side of the mouth and the bottom dragged to cover the bottom. At the end, all mouth IAs covered the mouth images with a distance of at least 5 pixels between the edge of mouth image and any part of the IA. No two IAs overlapped.

Trait judgments

Selection of trait judgments to be included in this procedure was based upon salient judgments identified in the literature and those that might be particularly relevant to individuals with these genetic disorders. The major sources of these were Oosterhof and Todorov (2008), Sutherland *et al.* (2013), and Vernon *et al.* (2014). Selected judgments on which faces were to be rated were the extent to which each appeared 'dominant,' 'trustworthy,' 'attractive,' 'baby-faced,' 'aggressive,' 'intelligent,' and 'approachable.' Table 19 indicates the rationale behind the selection of each. Although prominent in the literature, 'youthfulness' was not directly included due to the young age of all face images.

Table 19 Rationales for use of traits

Trait	Rationale
Trustworthiness	Validated in models of Oosterhof & Todorov (2008), Sutherland *et al.* (2013), & Vernon *et al.* (2014). Clinical relevance to behaviours that challenge services.
Dominance	Validated in the model of Oosterhof & Todorov (2008) & Vernon *et al.* (2014).
Attractiveness	Contributor to youthful/attractiveness validated domain in the models of Sutherland *et al.* (2013) & Vernon *et al.* (2014).
Baby-facedness	Contributor to youthful/attractiveness validated domain in the model of Sutherland *et al.* (2013) & Vernon *et al.* (2014). Known to affect adults' attributions of behaviours.
Approachability	Only negative loadings in Sutherland *et al.* (2013) but no positive load elsewhere in the model.
Intelligence	Relatively low factor loadings in Sutherland *et al.* (2013). Clinical relevance to people with ID and GNSs.
Aggressiveness	Validated in model of Sutherland *et al.* (2013). Clinical relevance to behaviours that challenge services.

Procedure

Participants completed consent (Appendix J) and demographics forms. Participants were allocated to either the informed or uninformed condition at random using a random number generator and given a corresponding information sheet[5] (Appendix K). Participants were then verbally asked "what do you understand about the images you are going to see?"; every participant in the informed condition was then reminded that some images would feature people with a GNS. Informed participants were asked not to discuss this aspect of the research with other potential participants.

The computer procedure (Appendix L) was arranged into two parts, each of which began with a standard 9-point calibration and validation procedure with a maximum average error of 0.5˚ and a maximum individual error of 1.0˚ (as per the methodology of Peterson & Eckstein, 2012). Prior to the appearance of each face image a manual drift check was

[5] In error, 12 participants in the uninformed condition received consent forms displaying the project title, potentially spoiling the condition. 12 contributed data to the rate procedure, 6 to the eye-tracking procedure. None of these 12 indicated awareness of the presence of GNSs when asked prior to testing and it was therefore assumed that the error was not noticed and each was analysed within the Uninformed condition.

completed up to the maximum value of 1.0˚ (as per the methodology of Valuch *et al.*, 2015). Where it was not possible to achieve a check within this value within 10 seconds a recalibration was performed. This procedure meant that the first fixation point was standardised to be on the nose interest area for every image.

For the first part of the experiment, participants were asked to simply look at all seventeen face images one by one. Each image was presented three times, arranged in three blocks so that each of the 17 images was presented once before being repeated a second then third time. Image order was randomised within blocks. Data from the three blocks were averaged together for each IA to produce a set of single, combined IA scores.

For the second part of the procedure, participants were asked to look at face images without distractors and to rate each according to the trait judgments. Responses were arranged into trait blocks, such that participants rated all faces on one trait in turn before moving on to the next trait. Presentation order of the traits was randomised between participants, and the presentation order of face images was randomised within each trait block. Participants made trait ratings using a continuous vertical scale on which they could click anywhere between the two extremes to indicate the strength of their impression. This produced a possible score range (in pixels) from 1-505.

At the end of the experiment, participants were given a debrief form summarising the purpose of the research (Appendix M).

Analysis

Data were analysed using IBM SPSS for Statistics v.24. GNS and ASD data were analysed independently using their separate matched controls (based on availability of images from Peter Hammond). Factorial mixed ANOVAs were used in all analyses with information condition as a between-subjects variable and face type as a within-subjects variable. Separate analyses were conducted for: each trait rating; response times; total number of fixations; dwell times and percentages for each IA; and fixations and fixation percentages for each IA.

Huynh-Feldt corrections for non-sphericity were used throughout unless specified. Whilst ANOVA is considered to be reasonably robust to violations of the assumptions of linear parametric tests (e.g., Schmider *et al*., 2010), such as assumptions of normality and homoscedasticity, since these assumptions were violated in places, all significant effects were confirmed non-parametrically where possible. Owing to the large number of planned contrasts, a more stringent alpha level of 0.01 was adopted throughout. For all eye-tracking analyses data from each of the three viewing trials were averaged using the mean for each participant to produce one score per face. A statement of epistemological position is presented in Appendix G.

Ethics

Ethical approval for this project was obtained from the University of Leicester Ethics Sub-Committee for Psychology (Appendix N).

Results

Typically developing images

To check whether merging the results for the TD male and female faces would create an appropriate combined-TD control group, paired-samples t-tests were completed for planned comparisons (Appendix P). As it was more important here that Type II error be minimised, the alpha level was set at the less conservative 0.05 level. Results for trait ratings were in line with the literature on sex differences (Oosterhof & Todorov, 2008); the female face was rated as less aggressive $t(57) = -3.85$, $p < .001$, more approachable $t(57) = 2.03$, $p < .05$ and less dominant $t(57) = -2.55$, $p < .05$, No differences were found for other dependent variables, including all eye-tracking data. As a result, TD data were combined as planned for all analyses except trait ratings, where TD data were analysed separately. For trait ratings the male face was used as control to maintain consistency with the control image in the ASD comparison, and because the male image differed less from the experimental images on almost all measures and so provided a more conservative estimate of significant differences.

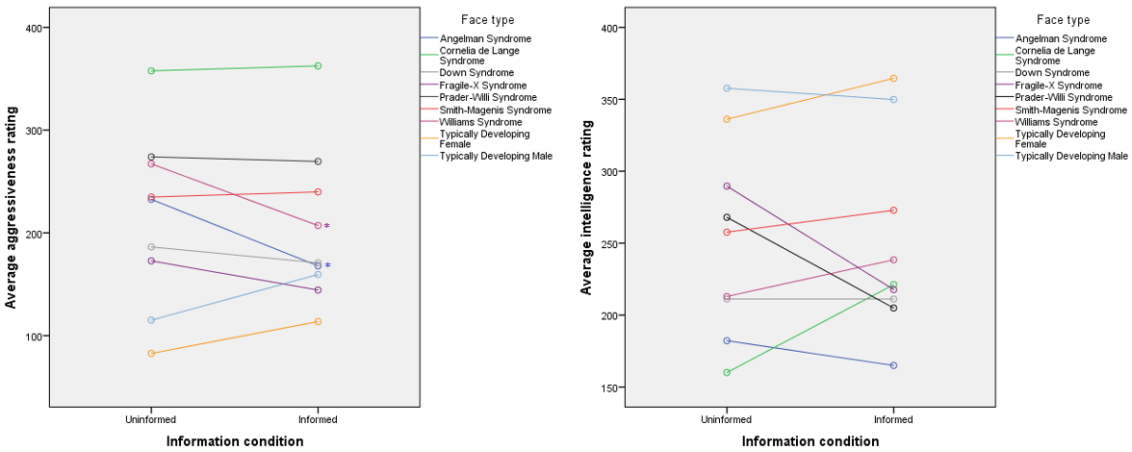
Trait ratings

Individual factorial mixed ANOVAs were completed separately for each rating type to identify which face images differed significantly from the male TD image on which traits. All main trait rating data tables are presented in Appendix Q. Main effects of face type were found for every trait rating (Table 20), indicating that every trait rating was affected by the face image participants were looking at whilst rating. These were confirmed by Friedman tests.

Table 20 ANOVA outputs of main effects of face type by trait rating

Trait rating	Df	F	*p*.
Aggressiveness	7.1	48.090	.000
Approachability	6.8	64.490	.000
Attractiveness	5.9	65.229	.000
Baby-facedness	6.2	19.159	.000
Dominance	6.7	29.007	.000
Intelligence	6.9	31.065	.000
Trustworthiness	6.9	49.973	.000

No main effects were found for information condition, indicating that no trait rating was reliably affected by informing participants about the stimuli. However for two traits an interaction was found between face type and information condition, indicating the effect of informing participants may be different for different faces: aggressiveness $F(7.1, 396.2) = 2.68$, $p < .05$; and intelligence $F(6.9, 385.6) = 3.52$, $p < .001$. Comparisons are presented in Figure 14 and suggest that informing people changed how participants rated the AS and WS faces on aggressiveness, with a marginal difference for FXS. No significant differences were found for intelligence, though differences for CdLS, FXS, and PWS approached significance. Significant differences were confirmed with Wilcoxon Signed Ranks tests carried out on data in which uninformed scores had been subtracted from informed scores; these comparisons also led to some other effects becoming significant (aggressiveness: FXS $Z = -3.19$, $p < .001$; intelligence: CdLS $Z = -2.85$, $p < .05$, PWS $Z = -2.62$, $p < .05$).



*Significantly different from Typically Developing male score at .01 level

Figure 14 Aggressiveness and intelligence ratings for face type x information condition

Simple within-subjects comparisons were planned between each face type and the male TD face, for each trait rating. The results are summarised in Figures 15 and 16[6]. All results were confirmed with Wilcoxon Signed Ranks tests. Of the comparisons made only seven did not differ significantly from the TD control image at the .01 level. Every GNS face was rated as significantly less approachable, attractive, intelligent, and trustworthy than the TD male face. This was also true for baby-facedness, except no significant difference was found for DS, and for AS the difference only approached significance. There was similarity in the pattern of results for aggressiveness and dominance, with DS and FXS not differing significantly from control on either rating. For dominance, AS also did not differ from control. CdLS, PWS, SMS, and WS face images differed significantly from TD across every trait measured.

[6] Although analysed as scores between 0-505, figures show data converted into percentage figures for ease of interpretation

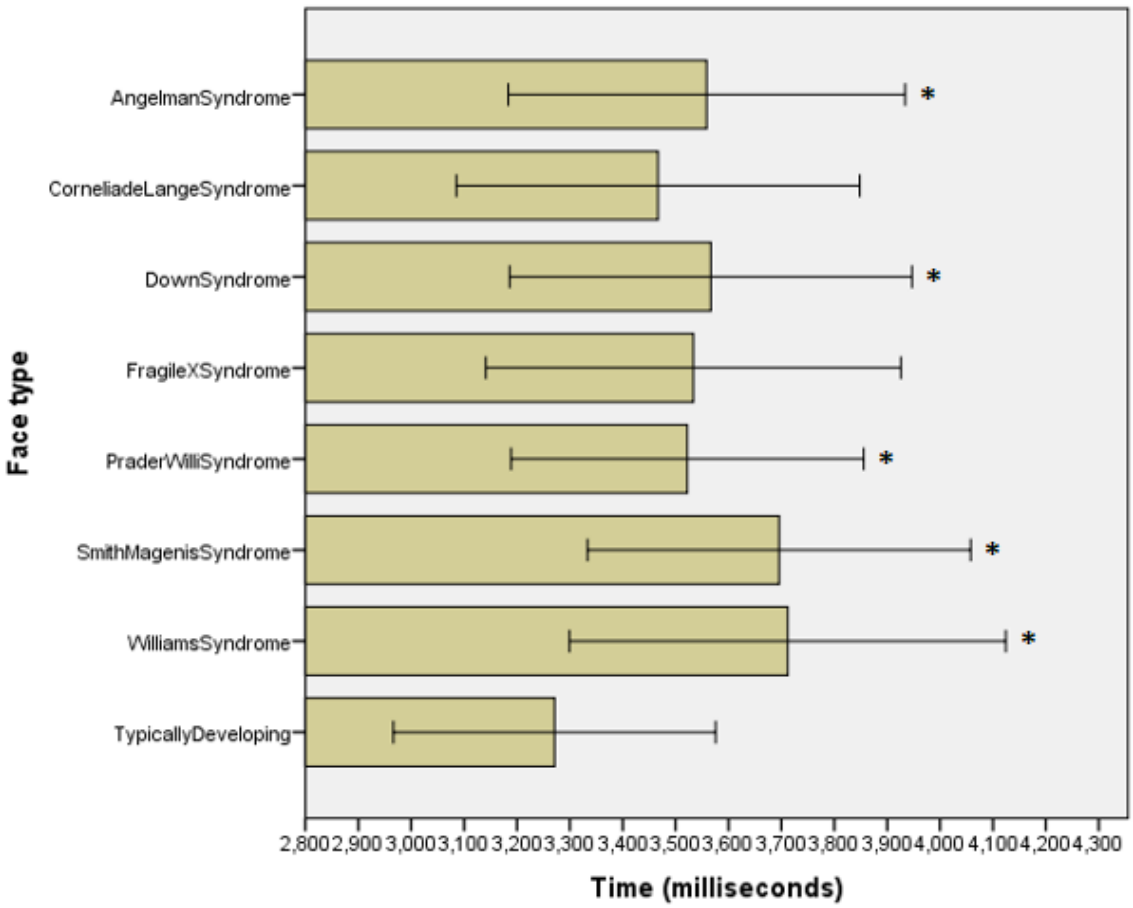
Figure 16 Average trait ratings by face type

Time taken to make trait ratings

A factorial mixed ANOVA with face type (within-subjects, 8 levels), trait judgment (within-subjects, 7 levels), and information condition (between-subjects, 2 levels) as independent variables and time taken to make trait judgments dependent variable was used. The main effect of face type suggested significant differences between facial images in the time taken to make ratings $F(7, 392) = 3.70$, $p < .001$. All faces representative of people with GNSs took significantly or near-significantly longer to rate than the TD images, except for CdLS and FXS (Figure 17). A Friedman test was used to confirm the main effect of face type and Wilcoxon Signed Ranks Tests were used to confirm the contrasts, each of which supported the parametric results. All other main and interaction effects were insignificant. All data output tables are presented in Appendix R.



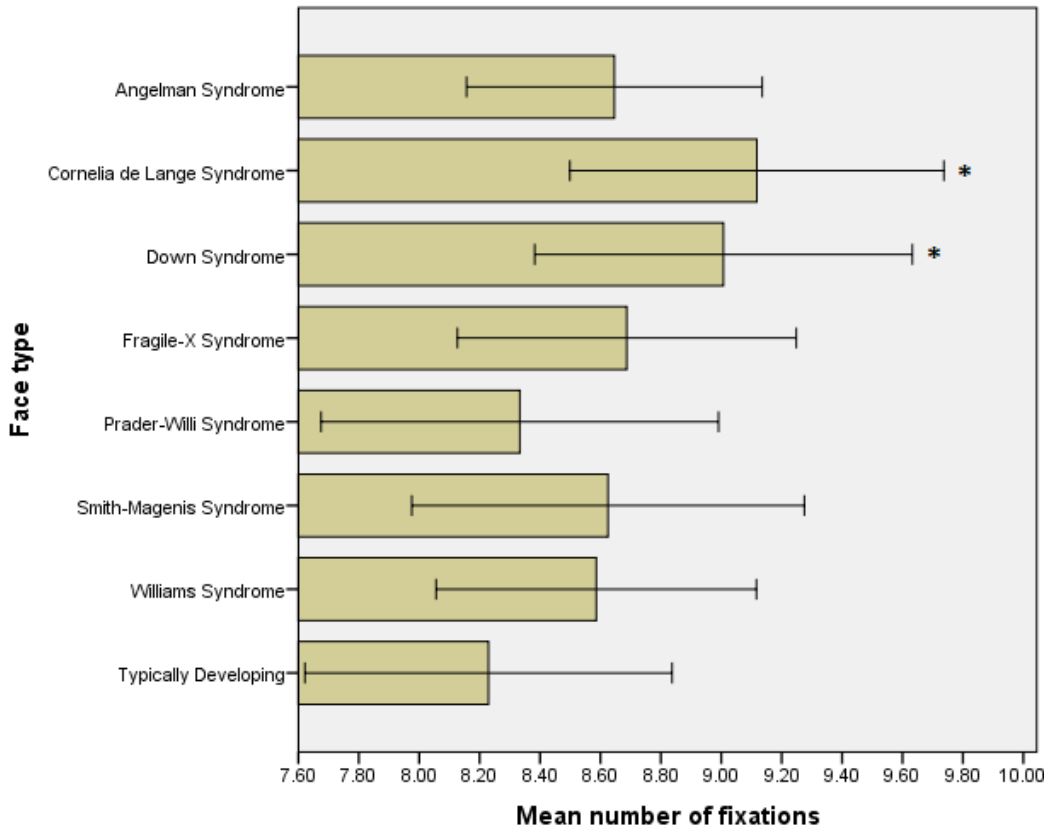
*Significantly different from Typically Developing score at .01 level

Figure 17 Mean time taken to make trait ratings by face type

Eye-tracking data

Number of fixations to the whole face

A factorial mixed ANOVA was conducted with face type and information condition as indendent variables and total number of fixations on faces during the view-only procedure as the dependent variable (Appendix S). Face type and information condition were composed as before. A statistically significant main effect was found for face type F(6.3, 289.9) = 4.095, *p* = .000, which was supported by a Friedman test. No other significant effects were found. Within-subjects contrasts for the main effect of face type are presented in Figure 18. Comparisons showed that the CdLS and DS images differed significantly from the TD controls, attracting a greater number of fixations within the time. This suggests that participants looked around these images more and is suggestive of differences in how the images were processed. A Wilcoxon Signed Ranks test confirmed the significance of the CdLS and DS comparisons.



*Significantly different from Typically Developing score at .01 level

Figure 18 Average number of fixations by face type

Interest area data

Factorial mixed ANOVAs were conducted to compare the main effects of face type (within-subjects), information (between-subjects), and interaction effects on the number of fixations, percentage of fixations, dwell time, and dwell percent to the three face areas separately (both eyes, nose, mouth). Face type and information consisted of the same levels as elsewhere. Data tables are presented in Appendix T.

Both eyes

Mauchly's Tests of Sphericity indicated that the assumption of sphericity had not been violated and sphericity-assumed data are reported. A similar pattern of results was produced for each of the eye-tracking measures. All showed significant main effects for face type, confirmed by Friedman tests. There were no other significant main or interaction effects (Table 21). This indicated that there were differences in the attention paid to the eyes depending upon which face image participants were looking at.

Table 21 Significance results for eye data

	Fixation count	Fixation percent	Dwell time	Dwell percent
Face type	$F(7, 322) = 9.45$, $p = .000$*	$F(7, 322) = 10.15$, $p = .000$*	$F(7, 322) = 7.94$, $p = .000$*	$F(7, 322) = 8.77$, $p = .000$*
Information	$F(1, 46) = 5.19$, $p = .027$	$F(1, 46) = 5.19$, $p = .027$	$F(1, 46) = 6.22$, $p = .016$	$F(1, 46) = 5.48$, $p = .024$
Facetype x Information	$F(7, 322) = 0.63$, $p = .732$	$F(7, 322) = 0.20$, $p = .986$	$F(7, 322) = 0.28$, $p = .962$	$F(7, 322) = 0.20$, $p = .986$

Within-subjects contrasts identified that the AS and WS images differed from the TD images in attention paid to the eyes (Table 22). Figure 19 shows that in each case these faces received less attention to the eyes than other images. Wilcoxon tests confirmed comparison results.

Table 22 *p* values for within subjects face-type contrasts for eye data

Face type	Fixation count	Fixation percent	Dwell time	Dwell percent
1. AS	.000*	.000*	.000*	.000*
2. CdLS	.981	.045	.013	.018
3. DS	.051	.904	.668	.868
4. FXS	.867	.430	.126	.131
5. PWS	.166	.174	.046	.052

7. WS	.002*	.000*	.000*	.000*

*$p < .01$

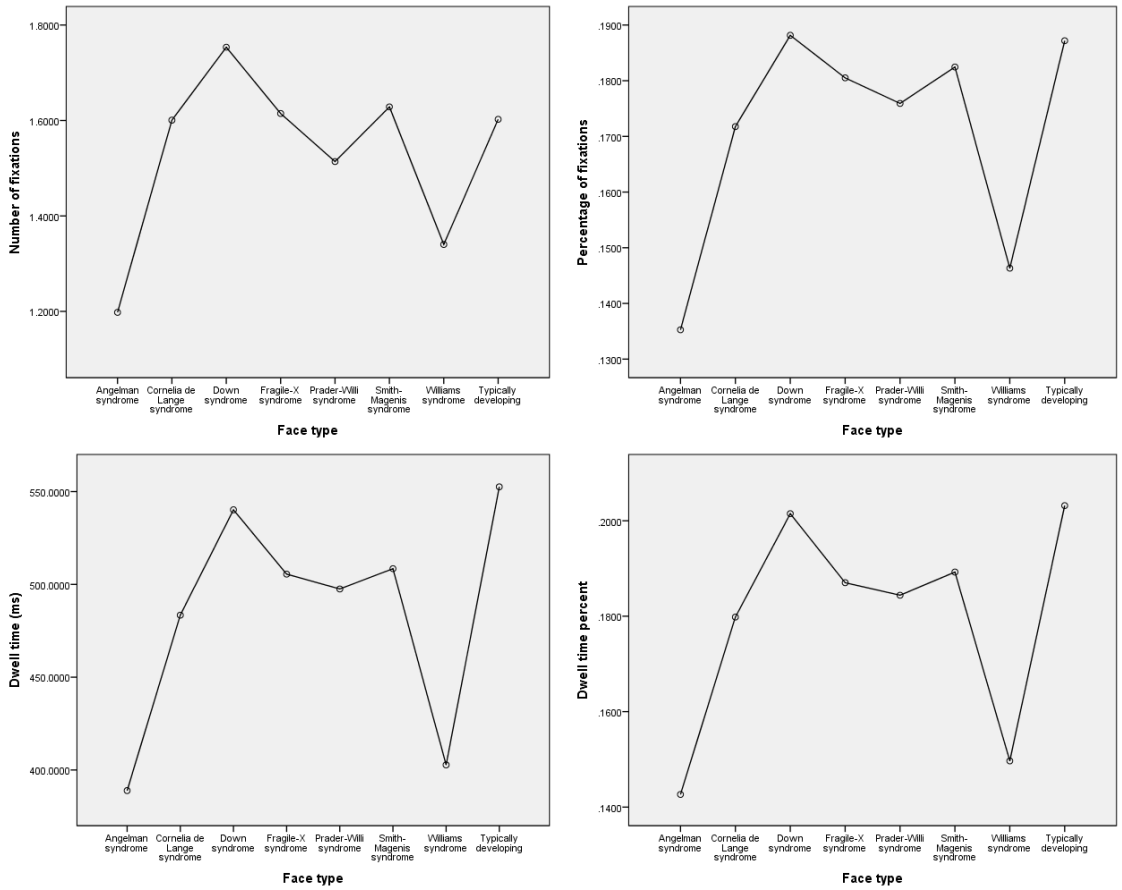

Figure 19 Mean eye data scores by face type

Nose

Sphericity-assumed results are presented for fixation data as Mauchly's test was not violated. Significant main effects were found for face type on dwell measures but not fixation measures (Table 23), however significant results became only marginally significant when repeated with Friedman tests: dwell time $X^2(7) = 17.923$, $p = .012$; dwell time percent $X^2(7) = 18.270$, $p = .011$. This suggests that participants may not differ markedly in how frequently

they looked at the noses of images, but they tended to remain looking at the nose of some faces more than others.

Table 23 Significance results for nose data

	Fixation count	Fixation percent	Dwell time	Dwell percent
Face type	F(7, 322) = 1.67, *p* = .115	F(7, 322) = 1.77, *p* = .093	F(6.6, 301.3) = 2.81, *p* = .009*	F(6.6, 302.9) = 2.85, *p* = .008*
Information	F(1, 46) = 4.05, *p* = .050	F(1, 46) = 1.90, *p* = .175	F(1, 46) = 1.33, *p* = .255	F(1, 46) = 1.92, *p* = .172
Facetype x Information	F(7, 322) = 0.36, *p* =.927	F(7, 322) = 0.48, *p* = .847	F(6.6, 301.3) = 0.38, *p* = .905	F(6.6, 302.9) = 0.46, *p* = .856

Within-subjects contrasts were completed on the dwell data to identify which faces differed from the TD images on dwell time and percent (Table 24). These revealed that no single image differed significantly from the TD images, though for PWS results approached significance, receiving more attention to the nose. Repeating the analysis using a Wilcoxon Signed Ranks Test led to these effects becoming significant Z = -2.759, *p* = .006, Z = -2.677. *p* = .007.

Table 24 *p* values for within-subjects face-type contrasts for nose data

Face type	Dwell time	Dwell percent
1. AS	.093	.110
2. CdLS	.895	.657
3. DS	.865	.925
4. FXS	.717	.873
5. PWS	.023	.015
6. SMS	.728	.660
7. WS	.396	.325

Mouth

Significant main effects were found for face type on every measure with no effect of information condition (Table 25). Friedman's tests supported significant findings.

Table 25 Significance results for mouth data

	Fixation count	Fixation percent	Dwell time	Dwell percent
Face type	F(6.3, 288.8) = 35.83, p = .000*	F(5.8, 265.1) = 34.82, p = .000*	F(5.2, 240.1) = 33.25, p = .000*	F(7, 322) = 34.34, p = .000*
Information	F(1, 46) = 1.62, p = .210	F(1, 46) = 1.97, p = .167	F(1, 46) = 1.19, p = .281	F(, 46) = 1.28, p = .264
Facetype x Information	F(6.8, 284.2) = 0.40, p = .886	F(5.8, 265.1) = 0.81, p = .562	F(5.2, 240.1) = 0.64, p = .675	F(7, 322) = 0.45, p = .870

Within-subjects contrasts suggested the inverse of eye data; the mouths of the AS and WS images were viewed significantly more than in the control images (Table 26, Figure 20). This suggests participants attended to the mouths at the expense of the eyes. FXS also had significantly more attention to the mouth than control. Wilcoxon Signed Ranks tests validated significant contrasts.

Table 26 p values for within-subjects face-type contrasts for mouth data

Face type	Fixation count	Fixation percent	Dwell time	Dwell percent
1. AS	.000*	.000*	.000*	.000*
2. CdLS	.072	.539	.315	.293
3. DS	.006*	.086	.246	.168
4. FXS	.000*	.000*	.000*	.000*
5. PWS	.499	.871	.251	.344
6. SMS	.038	.152	.044	.038
7. WS	.000*	.000*	.000*	.000*

Autism spectrum disorder image

Trait ratings

As with the GNS images, individual factorial ANOVAs were conducted to identify whether face type (ASD and TD) or information condition (informed or uninformed) impacted upon the seven trait ratings. Data tables are presented in Appendix U. One main effect of face type was found for baby-facedness $F(1, 56) = 17.25$, $p < .001$. The main effect of face type for dominance approached significance $F(1, 56) = 4.11$, $p = .05$. These effects were significant when repeated using Friedman Tests: $X^2(1) = 6.90$, $p = .009$; $X^2(1) = 9.931$, $p < .01$. Table 27 and Figures 21 and 22 show that the ASD face image was significantly less 'baby-faced' than the TD image according to the parametric analysis, and significantly more 'dominant' than the TD face when non-parametric analyses were undertaken. Means and standard deviations presented in

Table 27 are expressed as percentages. No other main or interaction effects showed significant differences between the ASD and matched TD face image.

Table 27 Means, standard deviations, and significance levels for trait ratings by face type

Trait	Mean *(SD)*		*p* value
	ASD	TD	
Aggressiveness	25.3 *(17.6)*	24.8 *(17.6)*	.796
Approachability	73.9 *(12.7)*	71.5 *(16.8)*	.303
Attractiveness	60.0 *(18.4)*	60.6 *(19.2)*	.705
Baby-facedness	70.5 *(18.6)*	78.2 *(16.4)*	.000*
Dominance	43.8 *(20.6)*	36.8 *(21.2)*	.047
Intelligence	65.7 *(14.1)*	64.0 *(20.2)*	.429
Trustworthiness	67.5 *(18.8)*	69.5 *(15.9)*	.379

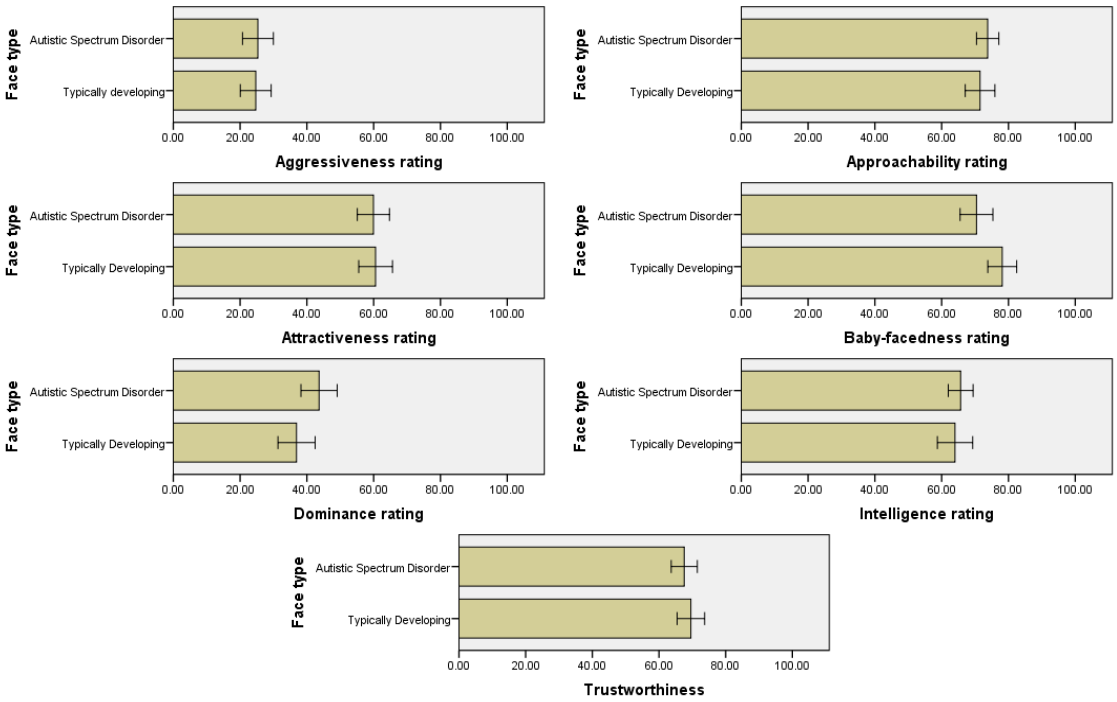

Figure 21 Average trait ratings by trait: ASD experiment

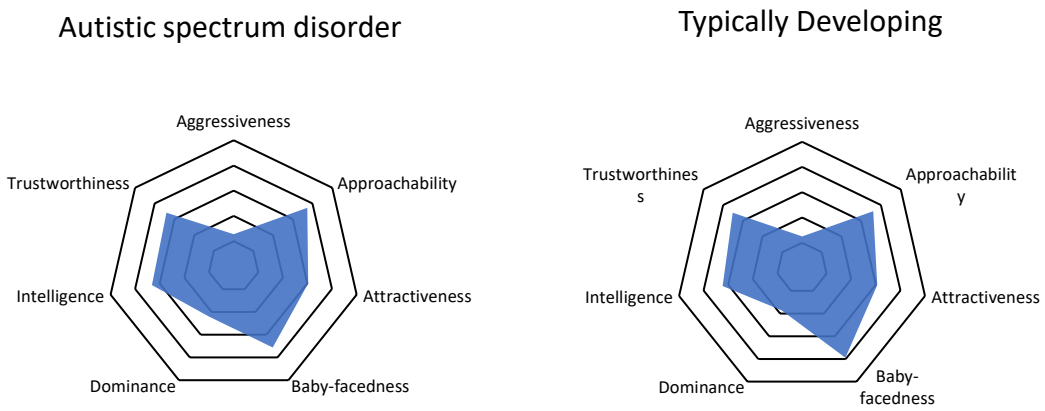

Figure 22 Average trait ratings by face type: ASD experiment

Time taken to make trait ratings

A factorial mixed ANOVA was conducted with independent variables of face type, type of judgment, and information on the dependent variable of time taken to make trait judgments. Data tables are presented in Appendix V. The levels of the ANOVA matched those for trait judgments. All main and interaction effects were insignificant: face type $F(1, 56) = 0.49$, $p = .487$; type of judgment $F(5.1, 287.8) = 1.07$, $p = .376$; information condition $F(1, 56) = .91$, $p = 0.344$, face type x information condition $F(1, 56) = 3.10$, $p = .084$, trait rated x information condition $F(5.1, 287.8) = 0.59$, $p = .714$, face type x trait rated $F(4.4, 245.4) = 0.95$, $p = .441$, face type x trait rated x information condition $F(4.4, 245.4) = 0.55$, $p = .715$.

Eye-tracking data

Number of fixations

A two (face type, within-subjects) by seven (judgment type, within-subjects) by two (information condition, between-subjects) mixed ANOVA was conducted with total number of fixations on faces during the view-only procedure as the dependent variable. Data tables are presented in Appendix W. No main or interaction effects were found; face type $F(1, 46) = 0.143$, $p = .707$, information condition $F(1, 46) = 1.170$, $p = .285$, face type x information

condition F(1, 46) = 1.170, *p* = .285. This indicated that participants did not differ reliably in how much they looked around the ASD and TD images.

Fixations and dwell times on interest areas

Separate factorial ANOVAs were conducted on face type and information for a) the number of fixations, b) the percentage of fixations, c) the time spent dwelling, and d) the percentage of time spent dwelling on each of the three face interest areas separately (eyes, nose, mouth) during the view-only procedure. No main or interaction effects were found on any analysis for eye-tracking data to interest areas. Data tables are presented in Appendix X.

Informal observations and debrief

During debrief, to identify whether they had remained naïve to the presence of GNSs in the image sample, each participant in the uninformed condition was asked the question: "was there anything else that stood out to you about the faces?" Of the 30 people in this condition, eleven spontaneously suggested that they had recognised that at least one of the faces represented a disability, ID, or a specific GNS. Four of these said that they only recognised that one of the faces represented a person with DS, and they did not recognise that the research concerned GNSs more generally. The remaining seven noticed that several faces were of people affected by these conditions, and in some cases commented that this affected how they responded to question items. Several participants commented upon the prominence of the eyebrows in the CdLS image and the mouths of the AS and WS images. As a result, it may be argued that the information manipulation was only partially successful owing to the recognisability of the facial profiles of people with GNSs.

Discussion

The results presented here have implications for the main questions outlined in the introduction section as follows:

1. Observed trait ratings suggest that there are differences in trait judgments made of face images representing people with a GNS and those representing typical development. The face image representing children with ASD diagnosis produced one significant trait judgment difference, for baby-facedness.
2. Differences were observed in the attention paid to the eyes and the mouths of certain GNS face images relative to TD, with less attention to the eyes for the AS and WS images, and greater attention paid to the mouths for AS, FXS, and WS images. No such differences were found for the ASD image.
3. The CdLS and FXS images attracted a greater total number of fixations than the TD face image. There were no significant differences for other GNS images or the ASD image.
4. There was no significant difference in trait judgments made of the faces depending on whether participants were informed about the presence of images representing people with a GNS or ASD diagnosis.
5. Face images representing people with a GNS, with the exception of CdLS and FXs images, attracted a greater number of fixations than TD images. No significant difference was found for the ASD image.
6. Informing participants about the presence of images representing people with a GNS or ASD diagnosis changed how participants rated the AS and WS faces on aggressiveness. Results also suggested that intelligence ratings were affected by which face was being looked at, but this did not appear to be driven by any individual GNS type.

Results suggest that judgments of facial stimuli representative of the morphology typically associated with a number of GNSs are likely to differ from judgments made about TD faces. The specific pattern of ratings differed for specific faces and all faces differed significantly from a corresponding TD image on most traits rated. Effect sizes for GNS trait rating data were

typically large, suggesting that facial differences had a strong effect upon trait inferences. It is interesting that the image representative of a child with ASD diagnosis also received a significantly different judgment rating in the area of baby-facedness despite the ASD label not being associated with either a consistent genetic marker or recognised diagnostically as having atypical facial morphology. In addition, people differed in the way in which they looked at the faces representative of people with GNSs: Where face images had markedly different morphology in the mouth, more attention appears to have been paid to those areas of difference at the expense of the amount of attention paid to the eyes. Eta-squared for eye-tracking data for GNS comparisons ranged 'medium'-'large-, however for ASD effect sizes for these tests was extremely small, indicating barely any impact of ASD diagnosis presence upon how faces were viewed by participants.

Every face resembling a child with a GNS or with ASD diagnosis was rated, relative to a matched image of a TD person, in a way that could have adverse repercussions for the individual in certain contexts. For some judgments, there is an obvious valence to the rating (e.g., trustworthiness, intelligence, attractiveness), although even for some of these there may be contextual factors at play. Higher perceived intelligence for example, may lead to reduced social distancing (Oullette-Kuntz, *et al.*, 2010), but may be problematic if it is inaccurate; it could mask difficulties, thereby impeding adaptations to suit individual needs, or lead to unrealistic attribution of responsibility in the context of behaviours that challenge services. For other ratings, the valence is less clear. Politicians, for instance, may benefit from a more dominant appearance, whereas the impact of this for someone in a caring profession may be the opposite. Also, whilst looking 'baby-faced' may benefit somebody in trouble, responsible professionals may gain advantage from looking less baby-faced. People with GNSs may be significantly disadvantaged by the types of automatic trait ratings that are made of them based solely upon their facial appearance; where a more obvious valence exists in a trait, GNS face images were universally rated more negatively. GNS images also took longer to rate,

suggesting that different facial appearance may make faces more difficult for participants to judge, or it could mean that participants were motivated to look at these faces for longer due to novelty. Differences for the ASD image were less pronounced than for GNS images and may potentially indicate perceptions of a less youthful or more masculine appearance (higher dominance) amongst people with that condition. This finding relating to the ASD image should arguably be treated with caution, as it is based upon only one image, and any two face images created separately would conceivably show structural differences, and therefore produce different trait inferences.

Only trait ratings of aggressiveness and intelligence appear to have been affected by whether participants were given advance knowledge of the presence of GNSs amongst the images presented, and this appears to have been driven by lower informed ratings of aggressiveness for the images representing AS and WS. There were no clear 'driver' images for intelligence. It is not clear why differences in aggressiveness ratings should be especially different for the AS and WS images. There were no other effects of information, and so participants did not appear to substantially alter their ratings or viewing behaviour dependent upon whether they knew GNSs to be present, except in these examples. This is perhaps surprising, as social demand effects may generally be presumed to impact upon data such as these. This suggests that participants' ratings may have related more to their perception of facial structure and what this might mean, than to their knowledge of GNSs, or it could be interpreted that judgments based on face structure are more unconscious and therefore less amenable to change owing to social desirability. It could also partially reflect that even 'uninformed' participants made assumptions about the face images that were concordant with the withheld information.

The differences in trait ratings observed may be consistent with previous research about how facial structure can impact upon judgments, particularly regarding overall facial

structure (Vernon *et al.*, 2014) and the extent to which structures are suggestive of emotional expression (Said *et al.*, 2009). Of the GNS groups, CdLS and PWS tended to be rated similarly across traits, often receiving the most extreme ratings of all faces on each trait. In particular, these faces were rated as more aggressive and dominant than other faces, which may correlate with a perception of masculinity (although all images were 'gender balanced'). A hostile emotional significance could have been drawn from the prominent brow of the CdLS image (Vernon *et al.*, 2014). Conversely, the FXS image shows a face with a slender jawline and larger eyes, features negatively associated with masculinity (Vernon *et al.*, 2014), and it was rated as no different to the TD image on aggressiveness and dominance on average. The differences in trait inferences made of the two 12-year-old TD faces were largely in line with what might be expected owing to sex differences, with the female face rated as less aggressive, marginally less dominant, more approachable, and more attractive than its male counterpart. One interesting finding that differed from expectation was that the AS image was rated as relatively untrustworthy and unapproachable, despite the picture being the only one to smile, a feature strongly positively associated with these ratings elsewhere (Sutherland *et al.*, 2003). This last finding may be influenced by other traits being read simultaneously into the face, such as those of low intelligence and high baby-facedness observed.

These results raise intriguing questions concerning the development of understanding of behavioural phenotypes amongst people with GNSs. AS, for example, is associated with a 'child-like and excitable' demeanor (Van Buggenhout & Fryns, 2009), and the ratings here of higher baby-facedness and lower dominance are remarkably concordant with that behaviour. As elsewhere, there is an indication that DS faced may be rated as more baby-faced than other types of GNS as it was one of the few faces not to differ from TD on this measure, whilst other GNS faces did. Baby-facedness in DS facial morphology has been associated with behavioural predictions of increased affection, naïvety, and compliance (Fidler & Hodapp, 1999), which in turn can lead to more favourable treatment (Zebrowitz *et al.*, 1991) and could help to

understand the observation that children with DS may avoid difficult tasks (Wishart, 1993). PWS was consistently rated as a more aggressive and dominant looking GNS, and has been particularly associated with 'temper tantrums' (Holland *et al.*, 2003). The less dominant and aggressive ratings of people with FXS correlate well with findings that they tend more towards internalising than externalising behaviours (Smith *et al.*, 2012). Finally, the 'extreme male' cognitive abilities of people diagnosed with ASD (Baron-Cohen, 2002) may be associated with the findings of lower ratings of baby-facedness plus the non-parametric significance of dominance ratings observed, but it would be inappropriate to infer that these data support arguments regarding dysmorphic facial development for people diagnosed with ASD.

The data here may also have ramifications for how behavioural phenotype research is conducted and results understood. The findings of different social judgments made of people suggests that even when people grow up in ostensibly the same circumstances, facial morphology may be one factor leading to people, on average, being treated differently and therefore to have different subjective experiences of objectively identical environments. The suggestion that any difference in how two individuals who have grown up in the same physical environment respond to identical situations being due directly to genetic factors is therefore further questionable in light of how physical differences between them can influence people's social worlds. In addition, this research also questions whether it is reasonable to rely on retrospective reports of behaviour in establishing phenotypes because such reports are likely to also be systematically influenced by biases related to assumptions about people's characteristics.

The eye-tracking data indicated that people tended to focus most of their attention upon the three main interest areas (eyes, nose, mouth). This is in line with previous research (Mertens *et al.*, 1993). They may also have tended to dwell disproportionately on areas of marked facial difference when looking at GNS faces, as in other research with people with

facial stigmata and orofacial clefts (Madera & Hebl, 2012; van Schjindel *et al.*, 2015), although since the facial gestalt is affected more generally in GNS, it is difficult to assess how this might compare to how people attend differently to individual distinctive marks. For the AS and WS faces, attention appears to have been drawn disproportionately to the mouth at the expense of attention paid to the eyes. Participants also appeared to look around faces with more prominent dysmorphic features; CdLS and DS faces gathered the greatest number of total fixations, with AS, FXS, and WS faces also receiving increased fixation rates. These findings may have clinical implications; previous research has associated attention to the eyes with empathy for faces (Cowan *et al.*, 2014). If atypical facial morphology distracts viewers from those parts of the face most expressive of emotion or pain, helpers may be less likely to show understanding and compassion in their responses.

Whilst it must be borne in mind that these are averaged ratings, made on averaged images under experimental conditions, the results gathered here may reflect significant repercussions on how people with GNSs or ASD diagnoses are treated, and on how behaviour is interpreted. Eye-tracking differences potentially indicate implicit social attitudes (Blais *et al.*, 2015), and trait judgments are likely to be present both in automatic (unconscious) and reflective (conscious) evaluative systems (see, e.g. Sherman *et al.*, 2014). The differences described in this report may therefore exert a consistent and subtle influence upon reciprocal interactions over long periods of time and between individuals (e.g. Zebrowitz *et al.*, 1991). Generally, appearance and visual scanning factors may be too subtle and too easily over-ridden by declarative processes to exert a substantial influence over interactions (Jarymowicz & Szuster, 2017), but may skew how people respond to situations in which declarative processes can be relied upon less. These include highly emotive situations and occasions in which fast, automatic reactions are required. Unconscious assessments amongst carers of higher aggressiveness or lower baby-facedness during difficult situations could conceivably lead to more punitive responses and feed patterns of troubling behaviour. As research

suggests that implicit attitudes may be accessible under certain circumstances (Hahn *et al.*, 2014), it may be of benefit to help clinical staff and carers identify their biases and develop strategies for mitigating their influence, for example by increasing access to reflective clinical supervision for front-line staff. The manner in which influences of facial morphology interact with other elements associated with GNSs, such as ID, is likely to be extremely complex and would require careful consideration.

The results here also have potential relevance to ongoing discussions and policy decisions relating to the social distancing of people with GNSs. That all GNS faces were observed to be rated as significantly less approachable, attractive, and trustworthy could arguably give additional clues as to why some people with ID experience exclusion. Observed biases in visual attention may lead to the exaggeration of perceived differences and this may not be ameliorated by knowledge of a person's condition. These data do not, however, account for familiarity with people with GNSs, and thus there is nothing here to suggest that greater contact between TD people and those affected by a GNS may not still offer a route into reducing social distance, and research with faces of typically developing people indicates that familiarity can lead people to rate them as more pleasing (Halberstadt *et al.*, 2013). It is also important to note that although this research identifies trends between groups of people, there is substantial variance in facial appearance within groups as well as between groups, and as such results pertaining to a group to which an individual belongs should not be assumed to apply equally to each person within that group.

The results here may be considered to be broadly relevant to children with the select GNSs identified, owing to the manner in which the images that were used were produced. While efforts were made to find a set of comparable photographs of individuals with other syndromes, those found were too few and variable (e.g. on lighting, definition, colour, age, etc.) to produce a reliable cohort for this experiment. By averaging a range of images into a

single image, the images used here offered a facial model that is likely to represent something of the general morphology associated with a condition. Use of these images does, however, also have limitations. Most notably, images were still, two-dimensional, and greyscale, so had less real-world validity and fewer more nuanced factors that affect how faces are interpreted in the real world, such as facial expression, body posture, movement, and social context. Also, variations within groups were naturally not represented. In addition, as a result of the averaging process there were many small discrepancies between face images that remained despite efforts to standardise them. For example, the image representing AS showed the face smiling and with an open mouth and it was not possible to get the eyes on the AS, DS, or ASD images to focus perfectly forwards. These discrepancies may arguably represent behavioural features of the syndromes, such as the 'happy demeanour' of people with AS, or reduced eye contact in people diagnosed with ASD, but the design of the study means it is not possible to assess the relative impact of the different elements of the images.

One variable that may arguably complicate interpretation of these results is facial expression. Facial expression is considered to be an important means of interpersonal communication (e.g. Frith, 2009), and research suggests that facial structure and expression may be more inextricable than might be assumed (Oosterhof and Todorov, 2009; Said *et al.*, 2009). When the images were being produced, children were asked to look at the camera but expression could not be consistently 'controlled,' and the face images were therefore not all 'neutral.' Facial expressions have been shown to exert significant effects upon character judgments (e.g. trustworthiness; Oosterhof & Todorov, 2008) and this is likely to have been a factor in trait ratings and eye-tracking data. Other than putative differences in emotional variables in behavioural phenotype research, there is little research into how emotion expression itself may differ between GNS groups. As results here indicate that some aspects of facial morphology skew perceptions based on face stimuli, it is possible that certain structures may also obfuscate facial expressions, making them more difficult to interpret. Reading

expression in faces may be particularly important for people with ID since, for instance, caregivers are encouraged to used facial cues to whether someone is unhappy or in pain, such as with the FLACC pain assessment tool (Malviya *et al*., 2005; Merkel *et al.*, 1997).

The information obtained in participant debrief offer some insight into how the results here should be interpreted. This mostly regards the lack of significant main effects of information condition. Since many participants in the nominally 'uninformed' condition realised the purpose of the study, either in full or in part, potential differences between the two groups may have reduced to the point of becoming insignificant. It is noteworthy that although insignificant, differences between the two group were still in anticipated directions, such that informed participants generally rated participants in ways that would arguably promote social inclusiveness (as less aggressive, more approachable, more attractive, more baby-faced, less dominant, and more trustworthy). The one rating that showed the opposite trend was intelligence, which had lower overall ratings in the informed condition, as might be expected if participants knew several of the participants to have a condition that could lead to ID. Observed power in the information main conditions and its interactions was small, and thus it remains possible that a real effect of knowledge of GNS influencing trait judgments exists, which the method employed here failed to detect.

There is a further consideration regarding the methodology of this project related to the trait ratings used. The wider literature from which they were drawn has focused mainly upon judgments made of the faces of adults. It is not necessarily the case that these judgments would be the same as those that would be made of the faces of pre-pubescent children. Indeed, during debrief, one participant reported that they found it unusual to be asked to make ratings of attractiveness and approachability for images representing children. In addition, the manner in which faces develop over time, and the possible psychosocial impacts of this in these groups, remains unstudied.

Future research would benefit from adapting the methods used here to incorporate more complex, and ideally more dynamic stimuli to increase ecological validity. It would also be helpful to repeat this project with images pertaining to people of a variety of ages (although fewer images exist due to increased diagnosis in younger age groups and higher levels of participation in research). Research into physiognomic judgments should aim to expand into different age ranges, such that we might better understand how children's faces are judged, and therefore how developmental trajectories could be affected by facial structure. The understanding of whether physiognomic trait judgments are implicitly or explicitly held remains quite basic, and controversies surrounding the relationship between implicit attitudes and real-world behavioural change makes it difficult to draw reliable inferences, and should be elucidated. Finally, research that seeks to report on means of decreasing social distance through educational programmes or facilitated contact between groups, or on mitigating the impact of implicit biases in care settings may be enhanced by considering the influences that these types of trait inferences may present.

To conclude, people with genetic neurodevelopmental syndromes such as Down syndrome, Fragile-X syndrome, and Angelman syndrome face a number of social challenges relative to typically developing people that research suggests commonly result in heightened risk of negative stereotyping and social exclusion. The research presented here suggests that the aetiology of these difficulties may include the types of social judgment systems that people develop for interpreting faces. People from these groups are likely to have a facial gestalt that differs from people who are unaffected, and these morphological differences appear to lead to different physiognomic assessments, such that an individual may be perceived to be more aggressive or less intelligent based upon how they look. Such differences are likely to relate to the meanings derived from facial structures, such as mouth size, and the extent to which facial features appear to resemble emotional expressions. A pattern of divergent physiognomic trait ratings for people with autism spectrum disorder may also exist,

in a manner supportive of theories that diagnosed people may have been exposed to higher levels of masculine hormones during development, but this requires further exploration.

Part C: Critical Appraisal

Finding clinical meaning in academic work.

Introduction

The following is a series of reflections upon the process of conducting the projects that have come together into this report. The information contained within it is based upon my note-taking and memory.

Why this area of research?

I began the clinical doctorate course without a clear idea of what I wanted to work on for my thesis. I felt acutely aware that I had not engaged in formal research since my undergraduate degree, which ended six years prior to the course, and thus did not feel confident in research methodology. I admit that as a result of this my priorities were practical moreso than ideological; I wanted a project that might be fairly contained so that I would be able to balance it effectively with clinical requirements of the course.

As a result, of the thesis topics pitched I was intrigued by one that highlighted differences in how facial appearance has been shown to affect social judgments, and the ramifications these have been shown to have for the people judged. I hoped this would be the containable project that would enable me to develop my research skills whilst also educating me about unconscious biases. Having worked in intellectual disability services before, I was interested in exploring how this type of research might pertain to goups of people who are already prone to social disadvantage and especially subject to the machinations of social power wielded by people around them. It also struck me that facial appearance is arguably more important today than ever, with profile pictures and social media relying upon facial appearance often being the sole visual representation of a person (Vernon *et al.*, 2014). As such this project also seemed like it might provide a potential vehical to offering an insight into something that could benefit clinical populations in the real world.

The research proposal

"Craig's doing an undergrad project" – a fellow student

A key consideration at this stage was the balance between how 'clinical' and how 'academic' the research would become. Research is a core component of clinical psychology training (Davey, 2003) yet working on a thesis subject matter too far removed from direct clinical environments may have limited my development as a clinical, as opposed to a research psychologist. Thus, through the early planning processes I held the balance of clinical and academic focus as a key consideration and evaluative concept under which I assessed the usefulness of developing ideas.

The original research proposal that was submitted to the course was quite different to the project that emerged. I think this is because I was quite ambitious about what might be achieved, and how I might make research on this topic more useful for clinical staff. Initial areas of interest focused on more dynamic and expressive stimuli, owing to my impression that static stimuli are rarely encountered by clinicians, however there weren't resources available. The proposal included two major projects, the first an implicit association test procedure aiming to highlight subconscious attitudes, and the second an idea about finding out whether people who are more familiar with these syndromes may react differently to people who are not, based upon the idea that contact and prejudice are likely linked (Allport, 1954). I hoped that focusing on implicit biases, and what might affect them, might serve the function of highlighting to clinicians a problem that probably exists and would impact upon clinical responses and decision making.

Feedback on the proposal was received from peer and lay reviews. I found that those involved in the peer review shared some of my concerns regarding clinical relevance. It was highlighted that framing the project as an attempt to highlight implicit biases and to contribute to social circumstances of affected people would be of sufficient clinical relevance.

The lay review, however, did not present any such qualms, and was encouraging in its feedback that people attending services would be helped by a project that identified and explored how anybody might have different subjective experiences of treatment from the same provider. Another consideration came from the peer reviewers about the ambition of the project, it was discussed as potentially too ambitious and the second project was highlighted as probably needing to be removed. This, however, would remove the more obviously 'clinical' part of the project.

Ethical considerations were also important at this stage. There were some concerns about the images used. Although the images that we had to use were not of any real person, they were nonetheless representative of conditions that real people experience, and what is more they were images representing children. Although it is likely true that each of us make this kind of social judgment on a daily basis, being asked to disclose our opinions can be exposing and uncomfortable. This is particularly true when the subjects of the judgments represent vulnerable groups, such as those diagnosed with disabling conditions or children. I thus included in my plans an intent to debrief participants thoroughly so as to mitigate the impact of this issue, which went on to produce benefits in interpreting the results I did not expect and emphasised the importance of communication skills throughout research. I felt ultimately that the potential benefit to people affected by these conditions and the anonymity of participants balanced the ethical considerations.

A final consideration at the planning stage was that I do not and have not personally known people diagnosed with any of the genetic neurodevelopment syndromes discussed in the research. I was aware, therefore, that this project placed me in an unusual position of taking an interest in and becoming well informed about something that I knew nothing of experientially. This situation contributed to a feeling of me 'doing to' with this project, rather than 'doing with' or even 'doing for.' This was a source of tension between this project and my

development as a clinican, where I in every case tried ‘do with’ and thus helped me to better understand and reflect upon my stance towards service users as a clinical psychologist.

The Literature Review process

The early experience with the literature review was addled by repeated failed attempts to get a project off the ground. I hoped initially to find a topic centred upon the impact of atypical facial appearance upon the experiences of other groups, in anticipation that this would help me to better understand aspects that could be relevant to my project regarding people with genetic neurodevelopmental syndromes. Eventually, attempts were abandoned and owing to time pressures an ‘off the shelf’ project was selected. Again, however, I wondered about the balance of the clinical and the academic in the project, and by the fact that I had not met anybody with CHARGE syndrome, and would again be ‘doing to’ this group.

I found, however, that there was a similar thread between the two projects. Most notably, the use it might have for helping to inform clinicians about the potential influences there might be upon reciprocal interactions that could contribute to affected people having different experiences to others. The scale of the project enabled me to discuss a broad spectrum of behaviour of people with the condition and many papers highlighted how each facet can cause difficulties for individuals and their families or carers. It became apparent to me that it would be helpful to offer information that would help to elucidate the reasons why people with this condition might act as they do, and that in doing so I would be in part advocating for better understanding of this group.

The literature review as it materialised did, however, have some limitations that affected this last goal. For example, despite my efforts I had to conclude that there remained a frustrating lack of clarity in the behavioural phenotype described. This was because CHARGE is a highly variable condition, and there was a dearth of research that directly compared affected

people to people with similar difficulties due to other genetic syndromes or physical disabilities, most notably deaf-blindness. I did not feel confident to make allusions as to what impact genetic and environmental factors might have had upon behavioural outcomes. Another limitation was the observation that the research into people with CHARGE focused exclusively upon deficits observed in affected people. I did not find research that explained the atypicalities in terms of positive ways in which people might be experienced. This again raised for me the disparity between my developing stance towards people as part of clinical work, and that which I felt I was adopting in the pursuit of the research goals of clinical psychologist. I felt that this limited the possibility of the research to fully advocate for affected persons, describing them essentially in terms of degree or type of undesirability, when I thought some aspects of the results showed promise for a more nuanced and optimistic discussion of difference.

The research process

Difficulties in implementing the original ideas led to changes in the course the research project took. Implicit association tests proved too strict a format and could not accommodate a range of implicit judgments that might add colour to the understanding of how people would be treated. They would only be able to reliably identify whether observers had more ostensibly positive or negative reactions to certain faces, and I felt this was insufficiently useful, I felt, for clinicians. I sought to keep the core goals of the research the same, to identify biases in implicit attitudes and to find out what factors might influence or be influenced by them. Social judgments were in of themselves observed to be unconsciously held (e.g. Greenwald & Banaji, 1995) and thus would thus fit the remit, and a project was designed to simply ask participants about their judgments. I would attempt to display the consciousness of these judgments via informed and uninformed experimental conditions.

The second strand of the research developed into an intention to test whether the types of judgments made tally with differences in how people might make judgments and decisions, or how they might alter behavioural intentions to certain situations, based on faces alone. I felt that this second strand was important as it promised the most clinical validity and connected the first strand of the project to the real world, which it pertains to describe influences for. Unfortunately, the limitations of time within the clinical doctorate did, as anticipated in peer review, eventually result in this being dropped within the last month prior to submission. Owing to the capacity for this part of the project to link the research more neatly with clinical work, I found myself arguing for this strand to be continued even when it became obvious that it was not practical.

Data collection and analysis

Data collection felt like an artificial process, as it involved using a computer lab that was as disconnected from a clinical environment as it is possible to be. This re-emphasised for me how important it would be to try to make this project in some way useful for real people. I again found, however, that when discussing the project with participants during debrief, it was not difficult to produce a clinical justification for the project. Debriefing participants came to be a fairly robust experience, and I learnt several things about their experience of the experiment that aided me in interpreting the data, even forming its own small section of the results. Many appeared enthused by the potential to clarify unconscious biases amongst people encountering individuals with diagnoses or genetic neurodevelopmental syndromes or autism spectrum disorders. One participant talked of working regularly on inpatient wards with some of the patient groups. She told me that research such as this would be extremely valuable to her, as she recognises different behavioural features amongst the people she works with and felt constantly aware of her own shifting feelings in response to individuals, and even concerned that she might be responding in a ‘wrong’ way, but lacking in means with

which to understand her experiences. As well as aiding the research and helping me to understand its benefit to clinical practice, I felt the process of providing substantial debrief helped to offer participants some potential benefit to taking part in the project, which was otherwise just one in a series of experiments they are pushed into doing.

As this was a quantitative study, I anticipated that the process of collecting and analysing data would be challenging. As it transpired, I underestimated just how complex and time-consuming this would turn out to be. This was due to several reasons. During data collection, several issues with satisfactorily setting up the eye-tracking machine led to repeated delays and to several participants' data either being wholy or partially removed from the study and replaced. During data analysis, it became apparent that owing to the complexity of the results each aspect of the data would have to be analysed separately, and that parametric assumptions had been violated for the vast majority of individual analyses. Resolving this latter problem, whilst also trying to retain the capacity fo identify interaction effects, led to an extremely labour-intensive analysis strategy that resulting in a huge volume of individual analyses and data outputs. Each had to analysed and formatted for presentation in the report methodically. The time constraints these placed me under were significant, and likely resulted in the planned second part of the project having to be dropped.

Interpretation

"Where there are limitations, they don't have to be damning" – supervisor feedback

I think, owing to my reservations about the clinical applicability of the work, and therefore wanting to be cautious about how I interpreted what I had found in terms of real world ramifications and applications, early drafts of the research report were quite heavily focused on limitations. On reviewing this with my supervisor, it became quite apparent that this meant space was lost in the report for asserting what the evidence generated did show. I think this issue reflected my lingering dissatisfaction with a project that had not materialised

as clinical in direction. This was an important moment in my estimation of the report as a whole. In turning towards the implications of the research and arguing for them, I found it much easier to convince myself of its clinical merits. That the report offered humble but definite steps towards a growing understanding of how people from these disadvantaged groups may be influenced by and come to present to clinical services, and the implications these may have for their lives more broadly. In addition, I felt that my clinical perspective added to my interpretation of the results, for example in observing that ongoing research continues to focus upon the negatives of people with these conditions. Thus, I feel I have a greater appreciation of not only how research may influence clinical practice, but of how working clinically may inform research.

Final thoughts

Completing the two projects contained in this thesis ultimately achieved the rather basic goal I had set out with. I have attained a set of skills in conducting research and literature reviews that I will be able to draw upon in future practice as a clinical psychologist, and done this whilst balancing other requirements of the course. I think the projects have added a substantial amount more to my development as a clinician, however, than just these valuable skills. I feel more aware of the myriad reasons why research might be done, and of the messages that are conveyed by adopting one approach over another. I feel a greater appreciation of the need to confidently assert conclusions of research, as well as to express the important limitations that readers should bear in mind when considering clinical significance.

I feel like this project as a whole has developed into one which contributes to how clinical staff can understand how they work with people with these conditions. I think the case is made for reflecting carefully upon how staff and carers experience people and how those experiences might impact upon atttiudes and behaviour. I think that equipping people in this

fashion may help them to become more responsible for their actions (Holroyd, 2015). I also think that significant contributions have been made to the understanding of the behavioural profile of people with CHARGE syndrome, and that this consolidation of knowledge will assist in the understanding and treatment of affected people. Finally, I think useful reflections are offered on the messages conveyed by the practice of developing behavioural phenotypes, and encourage future researches to bear these in mind.

Although now I still have not come into direct contact with people affected by these conditions, I feel I now have a greater respect for the challenges faced by people from these groups, and a greater sense of responsibility as a clinician for attending to how I and my colleagues understand and interact with them. I hope that these projects convey these lessons, and that in doing so they make a significant contribution to the practice of clinical psychologists working in this field.

Appendices

Appendix A Guidelines to authors for journal targeted for literature review

Target journal: Journal of Intellectual Disability Research

Information retrieved on 23/03/2018 from:
https://onlinelibrary.wiley.com/page/journal/13652788/homepage/forauthors.html

Author Guidelines
Thank you for your interest in *Journal of Intellectual Disability Research.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.
Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium.
Content of Author Guidelines:
1. Editorial and Content Considerations
2. Ethical Guidelines
3. Manuscript Types Accepted
4. Preparation of Your Manuscript
5. Submitting Your Manuscript
6. Copyright, Licencing and Online Open
7. Post Acceptance
8. Post Publication
Quick links: JIDR Submission Site, Wiley's Resources for Journal Authors
Relevant Documents Colour Work Agreement Form
1. EDITORIAL AND CONTENT CONSIDERATIONS
Journal of Intellectual Disability Research is devoted exclusively to the scientific study of intellectual disability and publishes papers reporting original observations in this field. The subject matter is broad and includes, but is not restricted to, findings from biological, educational, genetic, medical, psychiatric, psychological and sociological studies, and ethical, philosophical, and legal contributions that increase knowledge on the treatment and prevention of intellectual disability and of associated impairments and disabilities, and/or inform public policy and practice.
The journal publishes Full Reports, Brief Reports and Systematic Reviews. Mental Health Special Editions are published quarterly. Narrative reviews and hypothesis papers are encouraged but authors should discuss the focus of their review with the Editor in Chief prior to submission to ensure it is appropriate for the journal. Submissions for Book Reviews are also welcomed. Case studies are **not**published by JIDR.
Journal of Intellectual Disability Research will feature four Annotation articles each year covering a variety of topics of relevance to the main aims of the journal or topics. Senior researchers, academics and clinicians of recognised standing in their field will be invited to write an Annotation for the journal covering an area that will be negotiated with the Editor in Chief, Prof. Chris Oliver, on behalf of the Editorial Team.
Peer Review Process
The acceptance criteria for all papers are the quality and originality of the research and its significance to our readership. Except where otherwise stated, manuscripts are double-blind peer reviewed by two anonymous reviewers and the editor.
Journal of Intellectual Disability Research attempts to keep the review process as short as possible to enable rapid publication of new scientific data. In order to facilitate this process, submitting authors are asked to suggest the names and current e-mail addresses of two potential reviewers whom you consider capable of reviewing your manuscript. In addition to your choice the journal editor will choose one or two reviewers as well. Suggestions will be requested via the submission system.
Authors who wish to appeal the decision on their submitted paper may do so by e-mailing the Editorial Office with a detailed explanation for why they find reasons to appeal the decision.
Plagiarism detection
• The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.
• Individual authors and researchers can now check their work for plagiarism before submission - please click here for details.

2. ETHICAL GUIDELINES

Journal of Intellectual Disability Research adheres to the ethical guidelines for publication and research summarised below.

Authorship and Acknowledgements

Authorship: Authors submitting a paper do so on the understanding that the manuscript has been read and approved by all authors and that all authors agree to the submission of the manuscript to the journal. ALL named authors must have made an active contribution to the conception and design and/or analysis and interpretation of the data and/or the drafting of the paper and ALL must have critically reviewed its content and have approved the final version submitted for publication. Participation solely in the acquisition of funding or the collection of data does not justify authorship and, except in the case of complex large-scale or multi-centre research.

Journal of Intellectual Disability Research adheres to the definition of authorship set up by The International Committee of Medical Journal Editors (ICMJE). According to the ICMJE authorship criteria should be based on 1) substantial contributions to conception and design of, or acquisition of data or analysis and interpretation of data, 2) drafting the article or revising it critically for important intellectual content and 3) final approval of the version to be published. Authors should meet conditions 1, 2 and 3.

It is a requirement that all authors have been accredited as appropriate upon submission of the manuscript. Contributors who do not qualify as authors should be mentioned under Acknowledgements.

Acknowledgements: Under Acknowledgements please specify contributors to the article other than the authors accredited. Please also include specifications of the source of funding for the study and any potential conflict of interests if appropriate. Suppliers of materials should be named and their location (town, state/county, country) included.

Ethical Approvals

Experimental Subjects

Experimentation involving human subjects will only be published if such research has been conducted in full accordance with ethical principles, including the World Medical Association Declaration of Helsinki (version, 2002 www.wma.net/e/policy/b3.htm) and the additional requirements, if any, of the country where the research has been carried out. Manuscripts must be accompanied by a statement that the research was undertaken with the understanding and written consent of each participant and according to the above mentioned principles. A statement regarding the fact that the study has been independently reviewed and approved by an ethical board should also be included. Editors reserve the right to reject papers if there are doubts as to whether appropriate procedures have been used.

All studies using human participants or animal subjects should include an explicit statement in the Material and Methods section identifying the review and ethics committee approval for each study, if applicable. Editors reserve the right to reject papers if there is doubt as to whether appropriate procedures have been used.

Ethics of investigation: Papers not in agreement with the guidelines of the Helsinki Declaration as revised in 1975 will not be accepted for publication.

Clinical Trials

Clinical trials should be reported using the CONSORT guidelines available at www.consort-statement.org. A CONSORT checklist should also be included in the submission material (http://www.consort-statement.org/mod_product/uploads/CONSORT 2001 checklist.doc).

Manuscripts reporting results from a clinical trial must provide the registration number and name of the clinical trial. Clinical trials can be registered in any of the following free, public clinical trials registries: www.clinicaltrials.gov, clinicaltrials-dev.ifpma.org/, isrctn.org/. The clinical trial registration number and name of the trial register will be published with the paper.

Conflict of Interest

Authors are required to disclose any possible conflict of interest. These include financial (for example patent, ownership, stock ownership, consultancies, speaker's fee). Author's conflict of interest (or information specifying the absence of conflicts of interest) will be published under a separate heading entitled 'Conflict of Interests'.

Journal of Intellectual Disability Research requires that sources of institutional, private and corporate financial support for the work within the manuscript must be fully acknowledged, and any potential

conflicts of interest noted. Please include this information under the separate headings of 'Source of Funding' and 'Conflict of Interest' at the end of your manuscript.
If the author does not include a conflict of interest statement in the manuscript then the following statement will be included by default: “No conflicts of interest have been declared”.

Source of Funding

Authors are required to specify the source of funding for their research when submitting a paper. Suppliers of materials should be named and their location (town, state/county, country) included. The information will be disclosed in the published article.

Publication Ethics

The journal is a member of, and subscribes to the principles of the Committee on Publication Ethics (COPE). Wiley's Ethics guidelines can also be found at http://exchanges.wiley.com/ethicsguidelines

3. MANUSCRIPT TYPES ACCEPTED

Original Research Articles

The main text should proceed through sections of Abstract, Background, Methods, Results, and Discussion. Reports of up to 4,500 words are suitable for major studies and presentation of related research projects or longitudinal enquiry of major theoretical and/or empirical conditions. Please note that articles exceeding 4,500 words will be unsubmitted immediately from the review process and the authors will be asked to reduce the length of the article.
Authors submitting articles should be guided by the following checklists prior to submission:
For observational studies: http://www.strobe-statement.org/?id=available-checklists
For diagnostic studies: (http://www.stard-statement.org/checklist_maintext.htm)

Qualitative Studies

Qualitative Studies are only considered if they have strong theoretical underpinnings and use an established method of data synthesis.

Systematic Reviews

The maximum word length for systematic reviews is 4,500 words. Authors submitting a systematic review are encouraged to assess the quality of their article against the PRISMA checklist prior to submission (http://www.prisma-statement.org/2.1.2 - PRISMA 2009 Checklist.pdf) or MOOSE guideline (insert link to MOOSE PdF). Further details on systematic reviews can be obtained from Prof. Richard Hastings (Editor); email: R.Hastings@warwick.ac.uk

Brief Reports

Brief Reports of up to 1,500 words are encouraged especially for replication studies, methodological research and technical contributions.

Annotation Articles

Annotation Articles should be no more than 5,500 words long including tables and figures and should not have been previously published or currently under review with another journal. The normal instructions to authors apply. The date for submission of the article should be negotiated with the Editor in Chief. An honorarium of £400 in total shall be paid to the authors(s) when the article is accepted for publication.
Three main types of Annotations will be commissioned: 1. Authoritative reviews of empirical and theoretical literature. 2. Articles proposing a novel or modified theory or model. 3. Articles detailing a critical evaluation and summary of literature pertaining to the treatment of a specific disorder.

Hypothesis Papers

A Hypothesis Paper can be up to 2,500 words and no more than twenty key references. It aims to outline a significant advance in thinking that is testable and which challenges previously held concepts and theoretical perspectives. Hypothesis papers should be discussed with the Editor in Chief prior to submission.
*Please note JIDR does not publish **Case studies.***

4. PREPARATION OF THE MANUSCRIPT

Author Services

Prior to submission, we encourage you to browse the ‘Author Resources’ section of the Wiley ‘Author Services’ website: http://olabout.wiley.com/WileyCDA/Section/id-827998.html. This site includes useful information covering such topics as copyright matters, ethics and electronic artwork guidelines.

Writing for Search Engine Optimization

Optimize the search engine results for your paper, so people can find, read and ultimately cite your work. Simply read our best practice SEO tips – including information on making your title and abstract SEO-friendly, and choosing appropriate keywords.

Pre-submission English-language editing
Authors for whom English is a second language may choose to have their manuscript professionally edited before submission to improve the English. Visit our site to learn about the options. All services are paid for and arranged by the author. Please note using the Wiley English Language Editing Service does not guarantee that your paper will be accepted by this journal.
Spelling
• Spelling should conform to The Concise Oxford Dictionary of Current English.
• A high proportion of papers are submitted with the term 'behavior' as opposed to 'behaviour'; please use 'behaviour'.
• Where applicable the journal standard is to use words ending in –ise as opposed to –ize. For example, use 'analyse' 'standardise' as opposed to 'analyze' and 'standardize'
Units of measurements, symbols and abbreviations should conform with those in Units, Symbols and Abbreviations (1977) published and supplied by the Royal Society of Medicine. This specifies the use of SI units.
Terminology
It is important that the term 'intellectual disabilities' is used when preparing manuscripts. Please note that 'intellectual disability', as used in the journal, includes those conditions labelled mental deficiency, mental handicap, learning disability and mental retardation in some counties. The term 'person', 'people' or 'participant(s)' should be used as opposed to 'patient(s)'.
Optimising your paper on social media
If your paper is accepted for publication we would like to present three, headline style summary statements on our facebook and twitter feed. When you submit your article you will be asked to enter up to three short headlines (key statements) capture the importance of your paper.
MANUSCRIPT STRUCTURE
The manuscript should be submitted in separate files: title page; main text file; figures.
Title page
A 'Title Page' must be submitted as part of the submission process as a 'Supplementary File Not for Review. The title page should contain:
(i) a short informative title that contains the major key words. The title should not contain abbreviations (see Wiley's best practice SEO tips;
(ii) the full names of the authors;
(iii) the author's institutional affiliations at which the work was carried out;
(iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent;
(v) acknowledgements;
(vi) conflict of interest statement.
The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.
Acknowledgements
Contributions from anyone who does not meet the criteria for authorship should be listed, with permission from the contributor, in an Acknowledgments section. See section on Authorship for more detail. Financial and material support should also be mentioned Thanks to anonymous reviewers are not appropriate.
Main text
As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors.
The main text of the manuscript should be presented in the following order: (i) structured abstract and key words (ii) text, (iii) references, (vi) endnotes, (vii) tables (each table complete with title and footnotes), and (ix) figure legends. Figures should be supplied as separate files. Footnotes to the text are not allowed and any such material should be incorporated as endnotes.
Abstract
For full and brief reports, and reviews, a structured summary should be included at the beginning of each article, incorporating the following headings: Background, Method, Results, and Conclusions. These should outline the questions investigated, the design, essential findings, and the main conclusions of the study.
Keywords

The author should also provide up to six keywords. Please think carefully about the keywords you choose as this will impact on the discoverability of your paper during literature searches (https://authorservices.wiley.com/bauthor/seo.asp)

References

• The journal follows the Harvard reference style.
• References in text with more than two authors should be abbreviated to (Brown et al. 1977).
• Where more than six authors are listed for a reference please use the first six then 'et al.'
• Authors are encouraged to include the DOI (digital object identifier) for any references to material published online. See www.doi.org/ for more information. If an author cites anything which does not have a DOI they run the risk of the cited material not being traceable.
• Authors are responsible for the accuracy of their references.

The reference list should be in alphabetical order thus:

Giblett E.R. (1969) Genetic Markers in Human Blood. Blackwell Scientific Publications, Oxford.

Moss T.J. & Austin G.E. (1980) Preatherosclerotic lesions in Down's syndrome. *Journal of Mental Deficiency Research* **24**, 137- 41.

Seltzer M. M. & Krauss M.W. (1994) Aging parents with co-resident adult children: the impact of lifelong caregiving. In: *Life Course Perspectives on Adulthood and Old Age* (eds M. M. Seltzer, M.W. Krauss & M. P. Janicki), pp. 3–18. American Association on Mental Retardation, Washington, DC.

Endnotes

Endnotes should be placed as a list at the end of the paper only, not at the foot of each page. They should be numbered in the list and referred to in the text with consecutive, superscript Arabic numerals. Keep endnotes brief; they should contain only short comments tangential to the main argument of the paper.

Tables

Tables should include only essential data. Each table must be typewritten on a separate sheet and should be numbered consecutively with Arabic numerals, e.g. Table 1, Table 2, etc., and give a short caption.

Figure Legends

Figure Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparing Figures. Although we encourage authors to send us the highest-quality figures possible, for peer-review purposes we are happy to accept a wide variety of formats, sizes, and resolutions. Click here for the basic figure requirements for figures submitted with manuscripts for initial peer review, as well as the more detailed post-acceptance figure requirements.

Colour Figure Charges: It is the policy of *Journal of Intellectual Disability Research* for authors to pay the full cost for the reproduction of their colour artwork. Therefore, please note if there is colour artwork in your manuscript when it is accepted for publication, John Wiley & Sons Pte Ltd require you to complete and return a Colour Work Agreement Form before your paper can be published. Any article received by John Wiley & Sons with colour work will not be published until the form has been returned. If you are unable to download the form, please contact the Production Editor (jir@wiley.com)

Supporting Information

Supporting information is information that is not essential to the article but that provides greater depth and background. It is hosted online, and appears without editing or typesetting. It may include tables, figures, videos, datasets, etc. Click here for Wiley's FAQs on supporting information.

Please note that the provision of supporting information is not encouraged as a general rule. It will be assessed critically by reviewers and editors and will only be accepted if it is essential.

5. SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted electronically via the online submission site http://mc.manuscriptcentral.com/jidr. Further assistance can be obtained from Dr Jane Waite at the Editorial Office of JIDR, Cerebra Centre for Neurodevelopmental Disorders, University of Birmingham, Edgbaston, Birmingham, B15 2TT; Tel: 0121 414 7206; email jidr-admin@contacts.bham.ac.uk

• Launch your web browser and go to the journal's online submission site: http://mc.manuscriptcentral.com/jidr
• Log-in or click the 'Create Account' option if you are a first-time user.
• If you are creating a new account.
- After clicking on 'Create Account', enter your name and e-mail information and click 'Next'. Your e-mail information is very important.
- Enter your institution and address information as appropriate, and then click 'Next.'
- Enter a user ID and password of your choice (we recommend using your e-mail address as your user ID), and then select your area of expertise. Click 'Finish'.
• Log-in and select 'Author Centre'.

Submitting Your Manuscript

After you have logged in, click the 'Submit a Manuscript' link in the menu bar.
Enter data and answer questions as appropriate. You may copy and paste directly from your manuscript and you may upload your pre-prepared covering letter.
Click the 'Next' button on each screen to save your work and advance to the next screen.
You are required to upload your files.
- Click on the 'Browse' button and locate the file on your computer.
- Select the designation of each file in the drop-down menu next to the Browse button.
- When you have selected all files you wish to upload, click the 'Upload Files' button.

Review your submission (in HTML and PDF format) before sending to the Journal. Click the 'Submit' button when you are finished reviewing.

Manuscript Files Accepted

Manuscripts should be uploaded as Word (.doc) or Rich Text Format (.rft) files (not write-protected) plus separate figure files. GIF, JPEG, PICT or Bitmap files are acceptable for submission, but only high-resolution TIF or EPS files are suitable for printing. The files will be automatically converted to HTML and PDF on upload and will be used for the review process.

Blinded Review

To allow double-blinded review, please submit (upload) your main manuscript and title page as separate files.
Please upload:
- Your manuscript without title page under the file designation 'main document'
- Figure files under the file designation 'figures'
- The title page should be uploaded under the file designation 'title page'.

All documents uploaded under the file designation 'title page' will not be viewable in the HTML and PDF format you are asked to review at the end of the submission process. The files viewable in the HTML and PDF format are the files available to the reviewer in the review process.

Suggest a Reviewer

Journal of Intellectual Disability Research attempts to keep the review process as short as possible to enable rapid publication of new scientific data. In order to facilitate this process, please suggest the names and current e-mail addresses of 2 potential reviewers whom you consider capable of reviewing your manuscript. In addition to your choice the journal editor will choose one or two reviewers as well.

Suspension of Submission Mid-way in the Submission Process

You may suspend a submission at any phase before clicking the 'Submit' button and save it to submit later. The manuscript can then be located under 'Unsubmitted Manuscripts' and you can click on 'Continue Submission' to continue your submission when you choose to.

E-mail Confirmation of Submission

After submission you will receive an e-mail to confirm receipt of your manuscript. If you do not receive the confirmation e-mail after 24 hours, please check your e-mail address carefully in the system. If the e-mail address is correct please contact your IT department. The error may be caused by spam filtering software on your e-mail server. Also, the e-mails should be received if the IT department adds our e-mail server (uranus.scholarone.com) to their whitelist.

Manuscript Status

You can access ScholarOne Manuscripts any time to check your 'Author Center' for the status of your manuscript. The journal will inform you by e-mail once a decision has been made.

Submission of Revised Manuscripts

Revised manuscripts must be uploaded within three months of authors being notified of conditional acceptance pending satisfactory revision. Locate your manuscript under 'Manuscripts with Decisions' and click on 'Submit a Revision' to submit your revised manuscript. Please remember to delete any old files uploaded when you upload your revised manuscript. Please also remember to upload your manuscript document separate from your title page.

6. COPYRIGHT, LICENCING AND ONLINE OPEN

Accepted papers will be passed to Wiley's production team for publication. The author identified as the formal corresponding author for the paper will receive an email prompting them to login into Wiley's Author Services, where via the Wiley Author Licensing Service (WALS) they will be asked to complete an electronic license agreement on behalf of all authors on the paper.

Authors may choose to publish under the terms of the journal's standard copyright transfer agreement (CTA), or under open access terms made available via Wiley OnlineOpen.

Standard Copyright Transfer Agreement: FAQs about the terms and conditions of the standard CTA in place for the journal, including standard terms regarding archiving of the accepted version of the paper, are available at: Copyright Terms and Conditions FAQs. Note that in signing the journal's licence agreement authors agree that consent to reproduce figures from another source has been obtained.

OnlineOpen – Wiley's Open Access Option: OnlineOpen is available to authors of articles who wish to make their article freely available to all on Wiley Online Library under a Creative Commons license. With OnlineOpen, the author, the author's funding agency, or the author's institution pays a fee to ensure that the article is made open access. Authors of OnlineOpen articles are permitted to post the final, published PDF of their article on their personal website, and in an institutional repository or other free public server immediately after publication. All OnlineOpen articles are treated in the same way as any other article. They go through the journal's standard peer-review process and will be accepted or rejected based on their own merit.

OnlineOpen licenses. If the OnlineOpen option is selected the corresponding author will have a choice of the following Creative Commons License Open Access Agreements (OAA):

Creative Commons Attribution License (CC BY) OAA

Creative Commons Attribution Non-Commercial License (CC BY NC) OAA

Creative Commons Attribution Non-Commercial -NoDerivs License (CC BY NC ND) OAA

To preview the terms and conditions of these open access agreements please visit the Copyright Terms and Conditions FAQs.

If you select the OnlineOpen option and your research is funded by The Wellcome Trust and members of the Research Councils UK (RCUK) you will be given the opportunity to publish your article under a CC-BY license supporting you in complying with Wellcome Trust and Research Councils UK requirements. For more information on this policy and the journal's compliant self-archiving policy please visit: http://www.wiley.com/go/funderstatement.

7. POST ACCEPTANCE

Before your accepted article is published online, it goes through Wiley's production process. Wiley does everything possible to publish your article quickly and to the highest possible standard, as well as taking you through what to expect at each stage of the process.

Accepted article received in production

Your article is received at the publisher for production to begin. You (corresponding authors) receive an email asking you to login or register with Author Services. At this point, navigate to the "Amend My Details" page and choose whether you wish to:

• Publish your article open access with Wiley's OnlineOpen option

• Transfer the copyright of your article (if you do not publish open access)

• Track the publication status of your article (request to receive an e-mail alert at any, or all of the tracked stages of production)

• Nominate up to ten colleagues to receive a publication alert and free online access to your article (once published).

• Update your article with your ORCID iD.

Your publication checklist:

• Provide accurate proofreading and clearly mark any corrections as soon as possible.

• When prompted, ensure you acknowledge any funding support.

• Choose and arrange payment for open access as required.

• Sign a copyright license.

Copyediting and Typesetting

Wiley copyedit your article for style, grammar and nomenclature. Wiley also typeset your article, to make it look great.

Proofing and corrections

After copyediting and typesetting the article goes back to you. This is your chance to give your article a last look before it is published.

• A link to article proofs is provided via email.

• Accurately proofread your article and clearly mark any corrections online as soon as possible.

Please note that you are responsible for all statements made in your work, including changes made during the editorial process and thus you must check your proofs carefully.

Early View

The journal offers rapid speed to publication via Wiley's Early View service. Early View (Online Version of Record) articles are published on Wiley Online Library before inclusion in an issue. Note there may be a delay after corrections are received before your article appears online, as Editors also need to review proofs. Once your article is published on Early View no further changes to your article are possible. Your Early View article is fully citable and carries an online publication date and DOI for citations.

8. POST PUBLICATION

Access and sharing

When your article is published online:

• You receive an email alert (if requested).

• You can share your published article through social media.

• As the author, you retain free access (after accepting the Terms & Conditions of use, you can view your article).

• The corresponding author and co-authors can nominate up to ten colleagues to receive a publication alert and free online access to your article.

You can now order print copies of your article (instructions are sent at proofing stage).

Now is the time to start promoting your article. Find out how to do that *here.*

Measuring the Impact of your Work

Wiley also helps you measure the impact of your research through our specialist partnerships with Kudos and Altmetric.

Video Abstracts

A video abstract can be a quick way to make the message of your research accessible to a much larger audience. Wiley and its partner Research Square offer a service of professionally produced video abstracts, available to authors of articles accepted in this journal. You can learn more about it at www.wileyauthors.com/videoabstracts. If you have any questions, please direct them to videoabstracts@wiley.com.

Appendix B Specific rationales for database selection

PsycINFO

Description: Comprehensive database for psychology and related subjects

Rationale: High likelihood of retrieving articles relevant to behaviour

Medline

Description: Comprehensive database indexing biomedical literature.

Rationale: High volume of articles relating to people with CHARGE syndrome

EMBASE

Description: Comprehensive database indexing biomedical literature.

Rationale: High volume of articles relating to people with CHARGE syndrome

Appendix E Data extraction table

Table 32 Data extraction table

Author(s)	Date	n	Ages of CHARGE participants	Details about pps	Assessments	Comparison groups	Key relevant findings	Notes	Quality ratings	SI	CS	AC	GC
Abadie *et al.*	2000	17	2m-5y	Diagnosed 4 major /3 major and 3 minor	Physical assessment Parent questionnaire	Normal population using Brunet-LeÂsine scale.	1. Can't crawl w/o resting head on floor 2. Walking only: familiar place, flat/regular floor, outdoors 1yr late 3. DQ 44-50	Included	0.50				
Abi Daoud *et al.*	2002	30	13y-30y	None	Interview & questionnaire	None		Not included Quality rating too low	0.08				
Bernstein & Denno	2005	29	3y-21y	Physical features described	Compulsive Behavior Checklist	*Presumably normative data for the CBC*	1. 11.2 RBs pp 2. 72% 1+hours p/day in RPs 3. 72% interfered with social activities/relationships 4. 83% interfered with routine 5. 48% persevered following redirection 6. 34% responded to redirection with aggression 7. IQ: Average 3/29; Mild ID 8/29; Mod ID 11/29; Sev ID 7/29	Included *Also case study – added to low N*	0.33				
Blake & Brown	1993	39	18m-20y	Parents	Questionnaire	None		Not included Quality rating too low	0.25				

Blake *et al.*	2005	30	13y-30y	Physical features described	45 minute structured interview	None reported	1. walking 4.1yrs (SD=3.3). 2. 53% Socialising; 43% OCD; 37% Anxiety; 33% Tourettes; 33% PDD/Autism; 13% Conduct; 13% Depression; 10% ADHD; 7% Eating. 3. 53% Aggressiveness; 50% Self-abuse; 50% Sleep; 40% Tactile defensiveness 4. toileting 5.5yrs (SD=3.1); 5. Independence: 18/30, 16/30 dressing/toilet, 13/30 washing, 9/30 getting to work/school, 9/30 cleaning, 4/30 shopping, 0/30 cooking, 1 1/30 finances	Included	0.42				
Dammeyer	2012	17	0y-15y	Physical features described.	Questionnaire	Children with Usher Syndrome	1. Language delay – 3/17 severe; 11/17 Moderate; (3/17) none/little 2. Language– 9/17 Sign; 5/17 Oral; 1/17 Tactile; 2/17 pre-verbal 3. IQ – 2/17 IQ<50; 3/17 IQ=50-69; 12/17 IQ>69 4. Sleep– 8/17 'Lot'; 7/17 'Some'; 2/17 'No/few' 5. walking 38m	Included	0.50				
Deuce *et al.*	2012	44	1y-15y	Children diagnosed	Questionnaire	None	1. Sleep 6/44 2. Behaviour 5/44 3. OCD 4/44 4. ASD,2/44 5. Fearlessness 2/44	Included	0.42				
Dobbelsteyn *et al.*	2008	39	6m – 16y7m	Parents of	2 questionnaires	None	1. Swallowing difficulty 35/39	Included	0.58			
					Paediatric Assessment Scale for Severe Feeding Problems	None	Vomiting/gagging during/after feeding 29/37 at 1y, 17/28 1st grade, 1/5 7th grade	Included	0.50			
Forward *et al.*	2007	30	13y – 34y	Caregivers of people with CHARGE	Questionnaire	None	1. Adolescent more active when one-to-one care available.	Included	0.42			

					Habitual Activity Estimation Scale	HAES control data	2. 3-18y fewer active hours weekdays and weekdays (*P* = 0.001) 3. No difference for adolescents and older on weekdays.		0.50	
Graham *et al.*	2005	14	6 – 21 years	Boys only	Reiss Profile of Fundamental Goals and Motivation Sensitivities Achenbach Child Behavior Checklist (CBCL); Aberrant Behavior Checklist (ABC)	Age-matched boys: 20 DS; 17 PWP; 16 WS	1. CBCL CS v PWS - fewer internalising (p < 0.05), less withdrawn (p<0.5), fewer somatic (p<0.5) CS v WS & DS – more withdrawn (p<0.5), similar externalising [– PWS more aggressive (p < 0.001)] CS v WS & PWS – less anxious CS low risk maladaptive/aggression 2. ABC (means) Irritability, agitation = 9; Lethargy, social withdrawal = 6.71 (mod. high); Stereotypic behaviours = 5.21 (mod. high); Hyperactivity = 8.93; Inappropriate speech = 2.00. Boys with CHARGE highest irritability/hyperactivity, moderately high social withdrawal/stereotypic behaviours. 3. Reiss CS v DS & PWS & WS – lower social contact (p<0.01), higher maintaining order (p < 0.001), less help others (p < 0.5) CS v DS & WS – more frustration (p<0.001) CS v PWS & DS – less seek attention (p<0.01) CS v PWS – higher activity (p<0.5) 4. more likely to behave resembling ASD: socially	Included	0.66	

							withdrawn; low interest in social contact; reduced seeking of attention from others; hyperactivity; a need to maintain order 5. not as socially impaired as autism 6. Language not abnormal 7. Frustrated but not aggressive, few stereotypic behaviours/preoccupations. No restricted activities/interests." 8. due to dual sensory impairment rather than primary ASD						
Haibach & Lieberman	2013	21	6y – 12 y	None	Pediatric Balance Scale (PBS)	31 age, gender, sighted matched controls w/o CHARGE	1. ABC lower scores (p<0.001), correlated with PBS (r=0.56). 29 confidence balance 0/10. 2. more comfortable in familiar settings (M=8.95, SD=1.91) 3. walking 41.65m (SD=17.35)	Included	2-6 0.50				
		29	6y – 12 y	None	Self-efficacy of balance survey based on Activities-Specific Balance Confidence Scale (ABC)	31 age, gender, sighted matched controls w/o CHARGE	1. PBS CS performed significantly worse than control (p<0.05), 57% at med-high risk of falls	Included	0.58				
Hartshorne *et al.*	2016	53	13y-39y	participants and/or caretakers.	Questionnaire Impact of Childhood Neurologic Disability Scale; CDC Health-Related Quality-Of-Life (HRQOL) measure.	General US population data.	1. Walking 3.4y (SD=3.0) 2. Communication: sign 21/53, verbal 20/53, Sign/verbal 6/53, Gestures 4/53, Pictures 1/53. 3. Sleep 31/53, Aggression 27/53, Tac defensiveness 27/53, OCD 26/53, Self-injurious 25/53, Anxiety 24/53, ADHD 14/53,ASD 14/53, Tics 9/53, Conduct 7/53, Depression 4/53.	Included *2 case histories – sent to Amna*	0.42				

							4. HRQOL – Fair 8/53, Good 21/53, very good 16/53, excellent 8/53; 25% health restricted activities 5. Independence: Toileting 36/53, Dressing 32/53, washing 27/53 – Mixed: cleaning – Low: Getting to school/work (none 31/53), cooking 23/53, shopping 27/53, finances 36/53 6. Limitations due to: Hearing 46/53, Vision 37/53, Balance 28/53, Anxiety 19/53, Emotions 19/53), Walking 18/53. Sleep 15/53					
Hartshorne & Cypher	2004	100	Under 1y – 30y	95% by parents, 4 by others, 1 by individual with Charge.	Web-based, survey	ASD people, deaf-blind people.	1. 15/25 autistic disorder, 9/10 ADHD, 1/13 OCD, 15/21 deaf-blind, and 1/2 tic behaviours common	Included	0.33			
					71 behaviours 5-point likert scale	ASD people, deaf-blind people.	2. ADHD highest (3.0/5), ASD (2.7/5), deaf-blind (2.6/5), tic (2.5/5), OCD (2.0/5). 3. Categories correlated (0.66 ASD & deaf-blind) 4. Older more behaviours in ASD (r =.26 p<.001) and OCD (r =.23 p<025). 5. Medical conditions correlated with ASD (r =.22; p<.025), tics (r =.21; p<.05). 6. Age & walking correlated with behaviours (r =.20; p<.05), deaf-blind behaviours (r =.26; p<.001). 7. Deaf-blind more behaviours (p =.004), and on ASD (p =.02), deaf-blind (p =.002), and tic (p =.01). 8. Swallowing 74/100 Diagnoses: ASD 6/100; ADHD 7/100; OCD 3/100; Tourettes 2/100	Included .	0.50			

Hartshorne *et al.*	2009	87	6y – 18y	89.7% by mothers.	Sleep Disturbances Scale for Children (SDSC) Developmental Behaviour Checklist 2nd Ed. (DBC) Malaise Inventory (carer well-being).	Scale norms	1. SDSC 50/87 caseness, mean 60. high for 'sleep', 'sleep-wake transition disorders', 'sleep breathing disorders' 2. DBC 43/87 clin scores. Centiles for self-absorbed (64th), communication (62nd), and social (56th). Lower for Disruptive/antisocial (46th) and anxiety (48th). 3. Correlation SDSC and DBC (r=0.276; p =0.01). SDSC and self-absorbed subtest on DBC associated (r=0.444; p<0.001). 4. Parent well-being ass with sleep disturbance (r=0.316; p =0.003) and DBC (r=0.435; p<0.001) 5. Deaf-blind higher on SDSC (p=0.001), as did ear infections (p=0.015).	Included	0.42				
Hartshorne *et al.*	2007	98	5y - 18y	92.9% by mother.	Behavior Rating Inventory of Executive Function – parent version (BRIEF) Autism Behavior Checklist (ABC)	Scale norms	1. Delayed motor 96/98, swallowing probs 73/98. 2. BRIEF scale means elevated at except 'Organisation of materials' 50%+ significant scores on Shift, Monitor, and Behavioral Regulation. 3. Walking 3.08y, crawling 1.64y. walking associated with BRI: r =.23; MI: r =.29; GEC: r =.27… all p<0.5 4. BRIEF correlated with ABC (p<.01) except 'Organisation of materials.' ABC predictor for significant score on BRIEF (RSquare .15).	Included All participants previously involved in Hartshorne *et al.* (2005)	0.33				

							5. Deafblindness related to higher BRI (p<.05).						
Hartshorne *et al.*	2005	160	Under 3y – 33y		Autism Behavior Checklist (ABC)	Scale norms – norms from ABC for people with autism, and people who are deafblind.	1. 99% delayed motor, 79% swallowing 2. ABC scores lower than ASD (p<0.000) and higher than deafblind (p<0.02) 3. SD greater than other groups 4. 27.5% classified as autism 5. Age not correlated with ABC (r=0.07) 6. Correlation age walking and ABC 0.36 (p=0.000) – later walking higher ABC scores. 7. Deafblind highest ABC (p=0.000).	Included	0.50				
Hudson *et al.*	2016	20	2y-32y	Parents, 15 CHD7 mutation, 1 didn't, 4 untested.	Qualitative Phone interview	None	1. Dev delay 20/20 2. Food packing 15/20 3. Food in cheeks 7/20 4. over-stuff 19/20 5. 2/20 stuffing interfered with interactions 6. 2/20 stuffing manipulative 7. 5/20 not mix liquids&solids 8. 6/20 finish/3/20 routine 9. 3/20 anger and aggression 10. 4/20 eats quickly	Included	0.33				
Husu *et al.*	2013	18	1y-15y	All CHD7 mutation positive	Patient record review	TD norms	1. Developmental delay 11/13 2. delayed motor 13/13	Included	0.66				
Issekutz *et al.*	2005	77	Children and adults	Clinical diagnosis	Canadian Pediatric Surveillance Program (CPSP) – questionnaire.	TD norms and ASD norms 4 major (26) criteria and 3 or fewer (51)	1. OCD 7/16, Hyperactivity 7/16, Sleep 5/16. (14/16) feeding, 62% (10/16) GER, 75% (12/16) behavioural difficulties, 11/16 swallowing, Vestibular 7/16.	Included *Similar to Smith et al 2005 (also based on CPSP)*	0.92				
Johansson *et al.*	2006	31, 25 assessed for ASD	1m-31y	None	WISC or Vineland	TD norms	1. 17/25 ASD 2. 5 Childhood ASD; 4 IQ<20. 3. 5 ASD-like; 7 Traits; 2 ADHD	Included	0.42				

					Autistic Behaviour Checklist Autism Diagnostic Interview		4. Self-injury corr ASD $p<.05$; Hyperact corr ASD $p<.05$); 22/28 ID corr ASD $p<.001$) 5. Balance 21/24; Attention 10/28; impulsive 3/28; hyperactivity 18/28; self-destructivity 15/28; routines 19/28; stereotyped movement 14/28; aggressive 19/28; sleep 8/28; tics 2/28; aural interest 4/28; sensitivity to noise 5/28; visual interest 11/28; pain insensitivity15/28. 6. Visual impairment correlated with ASD ($p<.05$) and ID ($p<.001$) 7. Hearing impairment corr ASD ($p<.05$), not LD.	*This data appears to duplicate the results of Strömland et al (2005)*					
Lieberman *et al.*	2012	26	6y-19y	Parents	Questionnaire	None		Not included Quality score too low	0.25				
MacDonald *et al.*	2017	69	1y-18y	Parents, 17 had gene-positive diagnoses, rest clinical	Paediatric Assessment Scale for Severe Feeding Problems (PASSFP) Gastrointestinal Symptoms Scale (PedsQL) open-ended questions	TD norms	1. PASSFP – type of feeding reflected feeding difficulties 2. PedsQL –swallowing suggested levels associated with GI disorders 3. 18/54 over-stuffing *4. Many had difficulties consuming foods of varied textures, temperature, and consistencies.*	Included	0.50				
Miller *et al.*	2004	31	??	Clinical assessment-based diagnosis	Childhood Autism Rating Scale (CARS)	Mobius Sequence, Goldenhar/HFM Syndrome	1. 5/31 autism disorder and 5/31 autistic-like 2. no unique set of systemic malformations	Included *Strömland et al 2005 report on the*	0.75				

					Autistic Behaviour Checklist (ABC) Autism Diagnostic Interview-Revised (ADIR)			*same or similar data*					
Pagon *et al.*	1981	21	Not reported	Clinical assessment by specialist doctor	Clinical assessments	Comparable with TD norms	1. Swallowing 6/13 2. IQ score range 70 to 80 in 3 young adult males, to profound retardation in 4.	Included	0.58				
Raqbi *et al.*	2003	21	5y-12y	All met clinical criteria and were karyotyped, children with chromosomal anomalies excluded.	Neurological examination monthly during 1st year of life, 3months in 2nd,	None offered	1. bilateral coloboma resulting in low vision (p<.003), microcephaly (p<.02), and brain malformation (.002) predictive of poor intellect (severe neonatal medical conditions, long stays in hospital, and cardiac surgery were not). 2. psychomotor milestones 0-4yrs markedly delayed (hypotonia, poor arm use, diffs standing) (DQ=50)	Included	0.58				
					School performance and rehab requirements.	None offered	1. 5 IQ>70, 5 IQ 50-70. 6 IQ 35-49, 5 IQ < 35 2. 5 distractibility, impulsivity, inattention	Included	0.5				
Salem-Hartshorne & Jacob	2004	100	5y-15y	Parent-completed	CHARGE Parent Survey Adaptive Behaviour Evaluation Scale (ABES) by participants	Normative sample	1. ABES score = 73.7(SD=13.61), Range 55-110, Mode=55 2. Lowest Health 3.97, Self-Care 3.87, Home 3.83; Highest in Self-direction 6.52; Leisure 5.89, Social 5.07, Communication 5.06; Academics 4.74, Community use 4.51, Work 4.45. 3. ABES correlated with Walking age (r=.39, p<.01), Hearing (r=.23, p<.05), Medical	Included	0.42				

							involvement (r=.21, *p*<.05), Deaf-blind(r=.27, *p*<.05), not Vision (r=.17),						
Salem-Hartshorne & Jacob	2005	Two time points, 4yrs apart. 1st=100, 2nd=85	8y-20y	Parent-completed	CHARGE Parent Survey Adaptive Behaviour Evaluation Scale (ABES)	Normative sample	1. Time 1- ABES 71.9 SD=13.63 Time 2 –ABES 74.1 (T1/T2 r=.80). Range 55-107 50% (40/80) scored above 70, 13% (10/80) above 90 . 2. Age-adjusted scores declined over 4-years. 3. T2 correlations for Walking (r=.55 *p*<.01) and Medical involvement (r=.28 *p*<.01), not hearing/vision severity. 4. Age walking 3-5y 5. relationships of vision and medical involvement to adaptive behaviour because of effects on walking. 6. Lowest ABES scores in Home 3.13, Community use 3.21, and Academics 3.76; Highest self-direction 5.66, Leisure 5.55, and Communication 5.48. Social 4.69, Work 3.86, Health 4.08, Self-care 4.83.	Included *Time 1 (T1) scores are the same as those from Salem-Hartshorne & Jacob (2004)*	0.33				
Santoro *et al.*	2014	35	0-33.5y	All had CHD7 gene mutations 17 Nonsense, 12 Frameshift,, 2 Missense, 4 Splice site. 32 also clinical diagnosis Blake's criteria.	Progress Guide (Italian adaptation) .	Measure TD norms	1. Median lower in each domain. Greatest differences for oldest. 2. range of abilities up to 3 years variable. 3. median for development 50% except Feeding, Dressing, Toileting and Communication (poorer) 4. Washing best dev – 75%	Included .	0.66				
Souriau *et al.*	2005	71	6m-30y	Not explained	Questionnaire	None	1. Self-aggressive 28; Aggressive 27 2. Difficult to touch unstable sensory information.	Included	0.33				

							3. Difficulty walking on irregular surfaces associated vestibular 4. Hyperactivity 38/71. Association btw difficulty waiting and pleasure watching spinning (p<.001). 5. Need occupation corr enjoy objects spinning (p<.05). 6. Ass between throwing objects and difficulty social rules (p<.05). 7. Ass btw low understanding of social rules and touching people (p<.001). 8. Stability in info: affinity for jigsaw and need to put things away (p<.01). 9. Association btw depression and anxiety (p<.01). 10. Association btw self and others aggression (p<.01) 11. Corr btw isolating in group and with 1 person (p<.001) 12. Preference for 1:1 and being with adults linked (p<.01). 13. Diff with complex info

Appendix G Trainee's statement of epistemological position

All research is conducted under an epistemological position, whether this is implicitly held or explicitly reported. Epistemology refers to the means with which one might consider it possible to achieve knowledge, and the broader utility of that knowledge. Within the field of psychology, one might draw a rough line between postpositivist or realist positions, and those that assert that such a position is untenable or otherwise problematic (Creswell, 2009). The postpositivist position is that while we may aspire to absolute truth, we cannot be certain when studying humans. Thus, causes are considered to probably determine outcomes. Alternative positions hold that the aspiration of absolute truth is unrealistic, and that the best we can aspire to is descriptions of subjective meaning making. Quantitative methods tend to lend themselves towards postpositivist epistemologies, whilst qualitative designs favour alternatives (Creswell, 2009).

The epistemological position adopted for the purpose of this research project is a postpositivist position. This position was adopted because the aim is to make objective observations of how people react to certain stimuli, and to draw generalisable conclusions from those observations. The implicit assumption here is that the conclusions drawn may constitute a knowledge that has been drawn from a real, objective reality and that this knowledge pertains to that reality, which we all have access to and which we all share. There are necessarily limitations to this assertion. Most notably that only the data drawn constitute actual recordings of reality, and that the explorations of this data have been constructed by the author, using the language of wider research narratives in the broader literature, and so represents only one possible representation of this reality. Furthermore, the nature of the questions asked by this report and the choice of methods used to make observations have been informed by prior discourse on the issue and accepted standards.

Participant Consent Form

BACKGROUND INFORMATION
Title: How does different facial morphology affect how faces are perceived by others?
Researchers: Craig Griffiths, Trainee Clinical Psychologist at the University of Leicester School of Psychology. This project is supervised by Dr Alice Welham, Clinical Lecturer.
Purpose of data collection: Doctoral research

Details of Participation: This is an eye-tracking experiment that will involve you looking naturally at a series of faces and then answering some questions about the faces using the mouse. To do this experiment you will be asked to sit at a desk with your head on a chin rest. It would be helpful if you could keep your head fairly still throughout.
To start, it is important that we take some time to set up the equipment so that it can accurately track where you look. This is likely to take up to ten minutes and involve you looking at different spots on the screen. Sometimes glasses, contact lenses, and dark make-up can interfere with the equipment, to do the experiment you may need to remove them.
Once the eye-tracker is set up, the experiment itself should not take longer than 30 minutes.

CONSENT STATEMENT

1. I understand that my participation is voluntary and that I may withdraw from the research at any time, without giving a reason, up until the data has been combined in an analysis and it will no longer be possible to identify individuals. It is anticipated that data analysis will begin after 1st May 2017 so it may not be possible to withdraw data from that date. Should you wish to withdraw your data from the research you may do so by emailing cg277@leicester.ac.uk, giving your name and date of birth.
2. I am aware of what my participation will involve.
3. My data are to be held confidentially and only Craig Griffiths and Alice Welham will have access to them.
4. My data will be kept electronically for a period of at least five years after the appearance of any associated publications. Any aggregate data (e.g. spreadsheets) will be kept in electronic form for up to one year, after which time they will be deleted.
5. In accordance with the requirements of some scientific journals and organisations, my coded data may be shared with other competent researchers. My coded data may also be used in other related studies. My name and other identifying details will not be shared with anyone.
6. The overall findings may be submitted for publication in a scientific journal, or presented at scientific conferences.
7. This study will take approximately 18 months to complete in total.
8. I will be able to obtain general information about the results of this research by contacting the researcher via email after July 2018

I am giving my consent for data to be used for the outlined purposes of the present study. All questions that I have about the research have been satisfactorily answered.

I agree to participate.
Participant's signature: _____ Date: _____

Participant's name (please print): _____

If you have further questions about this study, you may contact Craig Griffiths at cg277@leicester.ac.uk This study was reviewed by the University of Leicester Psychology Research Ethics Committee (PREC). You may contact the Chair of
PREC Professor Panos Vostanis at pv11@le.ac.uk if you have any questions or concerns regarding the ethics of this project.

Appendix K Informed and uninformed participant information sheets

Informed

Procedure and Brief

This eye-tracking experiment is interested in the judgments we make when we look at other human faces. While using the eye-tracker, you will be asked to look at two separate presentations of computer-modelled face images. The faces vary in several ways, such as age and sex. Several of the images represent the faces of people with a range of genetic conditions, the rest represent the faces of typically developing people.

In the first part of the experiment you will be asked to simply look at the face images. Each image is shown for a set amount of time so you need not do anything but look at the faces. The equipment will record what you look at, in what order you look at different features, and how long you look for. Please just look at the faces naturally.

In the second part of the experiment you will be asked to rate face images according to personality traits and other attributes. You will need to use the mouse for this part of the experiment. The eye-tracking equipment will continue to monitor what you look at, in what order, and for how long, whilst you complete this part of the task.

As the eye-tracking equipment is very sensitive to light, darkness, and colour, several experimental conditions must be carefully monitored and maintained:

1. You will need to keep your chin upon the headrest and your head still during the face image presentations. Once the machine has been calibrated, please keep skill until the first presentation is over. The machine is set to recalibrate before starting the second presentation, so you may relax in between.
2. The lab will have to be in darkness during the experiment. Please let the experimenter know if you are uncomfortable with completing the test in the dark.
3. Dark eye make-up could disrupt the eye-tracker. During calibration (when the machine is calibrated to follow you eye movements) it may fail if make-up is worn. Unfortunately, this would require that eye make-up be removed in order for the test to proceed. Please ask the experimenter for eye make-up remover if you do not have any.
4. The equipment is sensitive to the presence of glasses and contact lenses, which may prevent the equipment from working. This would show up during calibration if it is a problem. If your visual aids disrupt calibration, and you are confident you will be able to see the presentation in detail without visual aids, these may be removed and the test can continue. If not, it will not be possible to proceed with the experiment.

Appendix L Computer procedure diagram

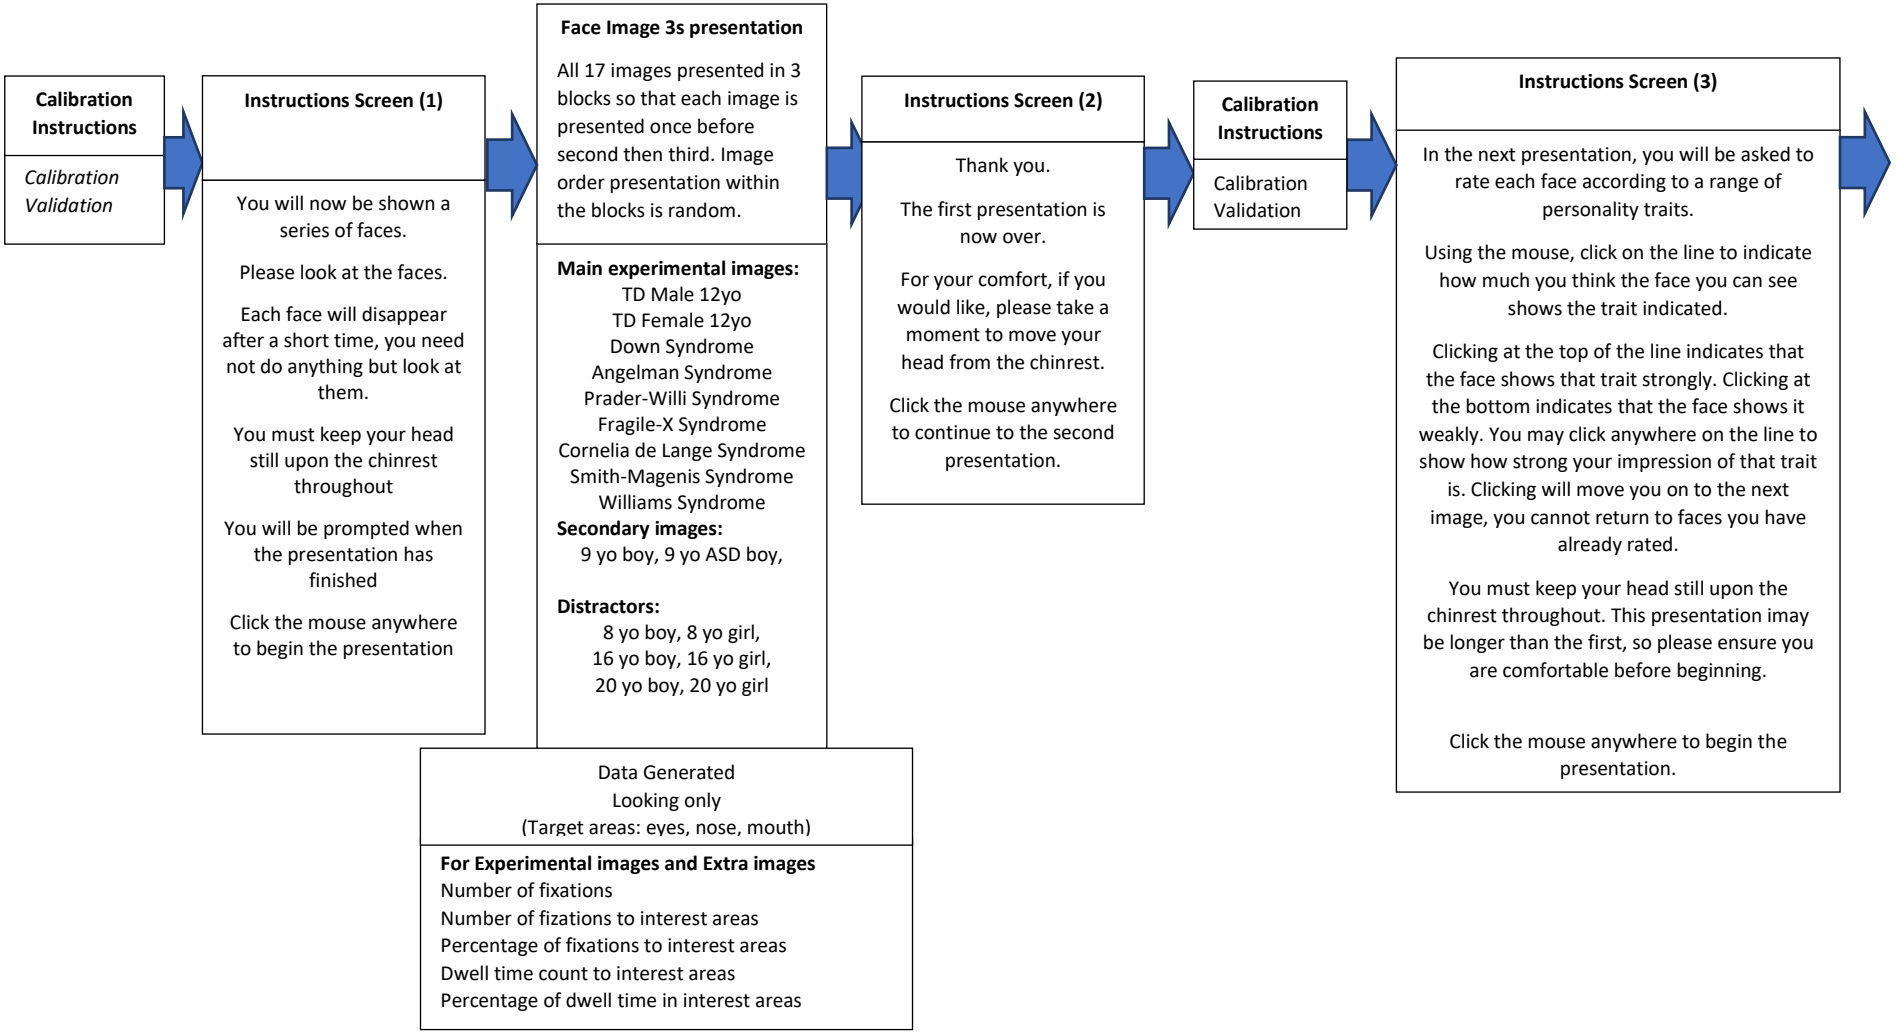

Figure 23 Computer procedure diagram 1

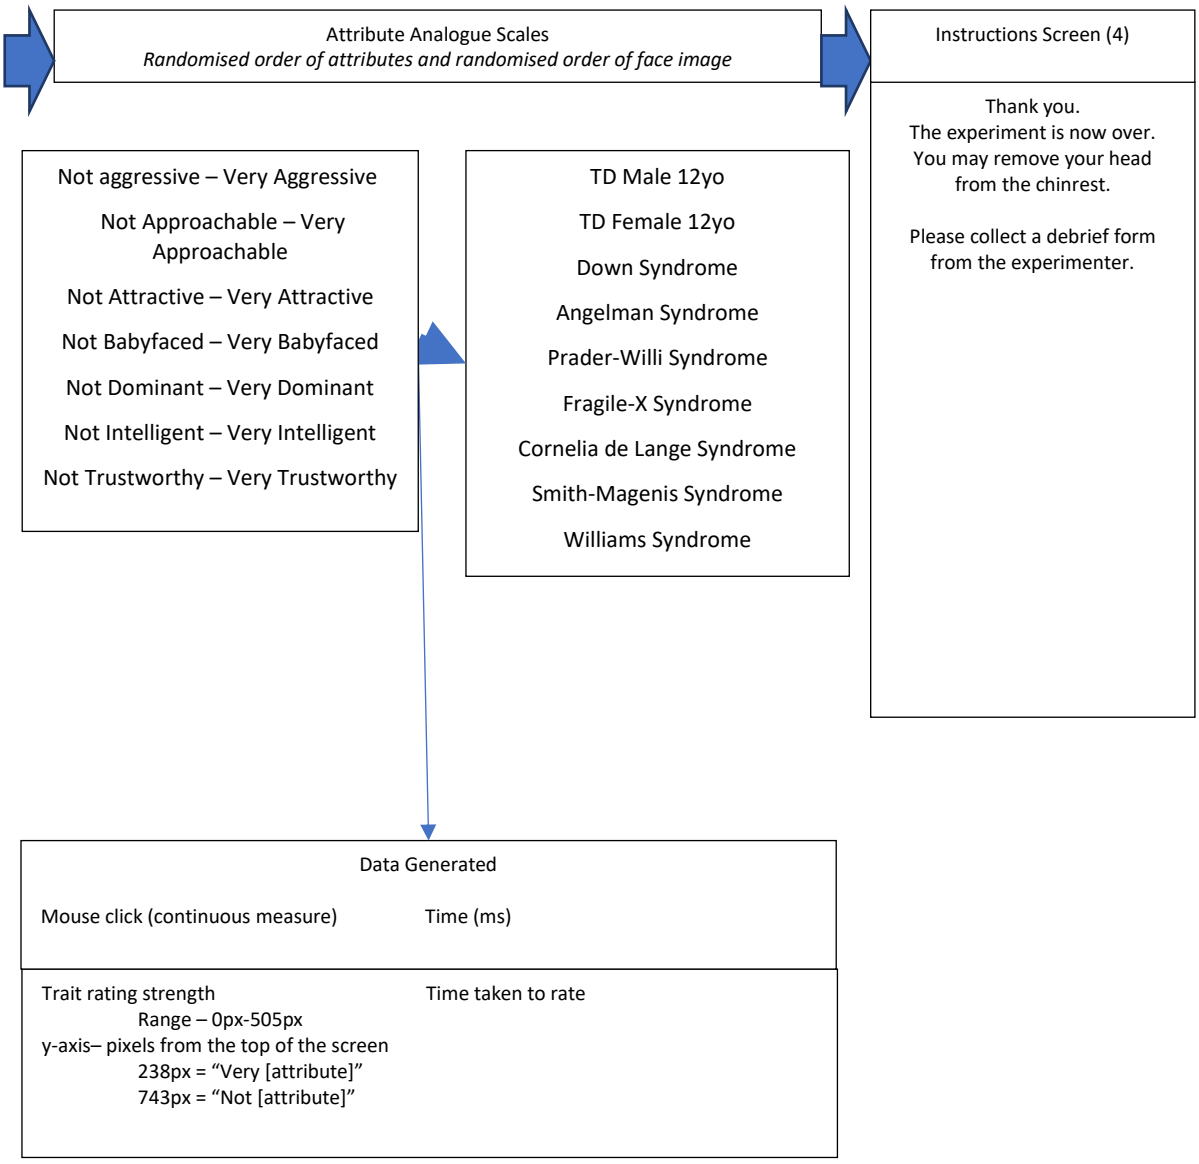

Figure 24 Computer procedure diagram 2

Appendix M Participant debrief form

Participant Information Sheet

What are the aims of the study?

We know from previous research that people make judgments about people based on what their faces look like. For example, faces with smaller eyes and stronger jawlines are judged as more dominant, and faces with bigger smiles are judged as more trustworthy (see, e.g. Vernon et al., 2014). This study aims to identify whether and in what ways people might make these types of judgments about people who have genetic disorders that reliably alter facial appearance. By looking at eye-tracking data, we hope to see whether people look at these face types differently, and whether this corresponds with different judgments. This might offer some insight into whether different judgments are automatic and unconscious, or if they are controllable (and potentially subject to social biases).

It is hoped that the information gathered in this project will help us to draw some conclusions that are relevant to the social treatment of people with genetic disorders including issues of discrimination.

Questions

- How can I contact the researcher if I have any further questions or if, for any reason, I wish to withdraw my data once I have left?

  Please email: cg277@le.ac.uk
- Can I obtain a summary of the results of the study? What form will this summary take?

  To obtain details of the results contact the researcher at cg277@le.ac.uk
- This study has raised personal issues that I am not comfortable discussing with the researcher now – what should I do? Support network details included below.

  If you feel you have been adversely affected by taking part in this study, and would like to speak to an independent support service you are advised to seek help from:

  The University of Leicester Student Counselling Service, 161 Welford Road.

  Telephone: + 44 (0) 116 223 1780

  E-mail: counselling@le.ac.uk

  Web: http://www2.le.ac.uk/offices/ssds/counselling
- I have concerns about this study, or the way in which it was conducted – who should I contact?

  In the first instance you should contact the supervisor of the project using the contact information provided above.

  Dr Alice Welham

  E-mail: akw12@leicester.ac.uk

  Clinical Lecturer

If your concerns are not dealt with then you can contact the Chair of the Psychology Research Ethics Sub-Committee in confidence by writing to:

Professor Panos Vostanis

E-mail: pv11@le.ac.uk

Chair of the Psychology Research Ethics Sub-Committee

School of Psychology

- Please feel free to ask the researcher any questions you might have prior to leaving the laboratory.

Appendix N Letters of ethical approval from the ethics committee

University Ethics Sub-Committee for Psychology

21/03/2017
Ethics Reference: [redacted]
TO:
Name of Researcher Applicant: Craig Griffiths
Department: [redacted]
Research Project Title: How does the different facial morphology of children with a range of genetic neurodevelopmental syndromes affect how they are perceived by others?

Dear Craig Griffiths,
RE: Ethics review of Research Study application
The University Ethics Sub-Committee for Psychology has reviewed and discussed the above application.

1. Ethical opinion
The Sub-Committee grants ethical approval to the above research project on the basis described in the application form and supporting documentation, subject to the conditions specified below.

2. Summary of ethics review discussion
The Committee noted the following issues:
This application is approved.

3. General conditions of the ethical approval
The ethics approval is subject to the following general conditions being met prior to the start of the project:
As the Principal Investigator, you are expected to deliver the research project in accordance with the University's policies and procedures, which includes the University's Research Code of Conduct and the University's Research Ethics Policy.
If relevant, management permission or approval (gate keeper role) must be obtained from host organisation prior to the start of the study at the site concerned.

4. Reporting requirements after ethical approval
You are expected to notify the Sub-Committee about:

- Significant amendments to the project
- Serious breaches of the protocol
- Annual progress reports
- Notifying the end of the study

5. Use of application information
Details from your ethics application will be stored on the University Ethics Online System. With your permission, the Sub-Committee may wish to use parts of the application in an anonymised format for training or sharing best practice. Please let me know if you do not want the application details to be used in this manner.

Best wishes for the success of this research project.
Yours sincerely,
[redacted]
Chair

Table 69 GNS - Trait ratings - Aggressiveness - Sphericity

Within Subjects Effect	Mauchly's W	Approx. Chi-Square	df	Sig.	Epsilon[b] Greenhouse-Geisser	Huynh-Feldt	Lower-bound
face_type	.250	73.628	35	.000	.765	.884	.125

Tests the null hypothesis that the error covariance matrix of the orthonormalized transformed dependent variables is proportional to an identity matrix.

a. Design: Intercept + I_OR_U
Within Subjects Design: face_type

b. May be used to adjust the degrees of freedom for the averaged tests of significance. Corrected tests are displayed in the Tests of Within-Subjects Effects table.

Tests the null hypothesis that the error covariance matrix of the orthonormalized transformed dependent variables is proportional to an identity matrix.
a. Design: Intercept + I_OR_U
Within Subjects Design: face_type + trait_ratings + face_type * trait_ratings
b. May be used to adjust the degrees of freedom for the averaged tests of significance. Corrected tests are displayed in the Tests of Within-Subjects Effects table.

Tests the null hypothesis that the error covariance matrix of the orthonormalized transformed dependent variables is proportional to an identity matrix.
a. Design: Intercept + I_OR_U
Within Subjects Design: facetype
b. May be used to adjust the degrees of freedom for the averaged tests of significance. Corrected tests are displayed in the Tests of Within-Subjects Effects table.
