1 Model Specification (Sparse Space-Time Autoregressive)

We consider the following Sparse Space-Time Autoregressive (SSTAR) model for R regions with the following specification (1), with the stack matrix formulation is defined here in order to derive the SSTAR specific forecast error impulse response function in the following section.

Our SSTAR consists of matrices $\mathbf{Y}_{t-i_1, (R \times 1)}$, $\mathbf{A}_{i_1, (R \times R)}$, $\mathbf{B}_{i_2, (R \times R)}$, $\mathbf{W}_{i_2, (R \times R)}$. In addition, we consider a diagonal time autoregressive matrix $\mathbf{diag}(\mathbf{A}_{i_1}) = \phi_{i_1, 1:R}$ with $\phi_{i_1, 1:R}$ entry denoting the i_1^{th} autoregressive coefficient for regions 1 to R , a diagonal time-space autoregressive matrix $\mathbf{diag}(\mathbf{B}_{i_2}) = \gamma_{i_2, 1:R}$ with $\gamma_{i_2, 1:R}$ entry denoting the i_2^{th} space-time recursive coefficient for regions 1 to R and a weight matrix with diagonal entries made to be zero $\mathbf{diag}(\mathbf{W}) = \mathbf{W}$ the distance/adjacency matrix between regions as described in the main text. We may also consider H exogenous variables $\mathbf{C}_{i_3, u, (R \times R)}$, with

$\text{diag}(\mathbf{C}_{i_3,u}) = c_{i_3,u,1:R}$ denoting the i_3^{th} lag of variable u associated to Y_t . P_1, P_2, P_3 are the number of lag terms associated to autoregressive, space-time recursive and exogenous coefficients respectively. Finally ϵ_t denotes the noise vector.

$$\mathbf{Y}_t = \sum_{i_1=1}^{P_1} \mathbf{A}_{i_1} \mathbf{Y}_{t-i_1} + \sum_{i_2=1}^{P_2} \mathbf{B}_{i_2} \mathbf{W} \mathbf{Y}_{t-i_2} + \sum_{u=1}^H \sum_{i_3=1}^{P_3} \mathbf{C}_{i_3,u} \mathbf{X}_{u,t-i_3} + \epsilon_t \quad (1)$$

It is easy to see that SSTAR is of seemingly-unrelated regression form by considering the model specification for the k^{th} row of Y_t for the k^{th} region (2), with estimation proceeding by considering the following equation by equation penalized minimization problem iteratively for all regions (3).

$$y_{t,k} = \sum_{i_1=1}^{P_1} \phi_{i_1,k} y_{t-i_1,k} + \sum_{i_2=1}^{P_2} \gamma_{i_2,k} W y_{t-i_2,-k} + \sum_{u=1}^H \sum_{i_3=1}^{P_3} c_{i_3,u,k} X_{u,t-i_3} + e_t \quad (2)$$

$$\underset{\phi, \gamma, c, \lambda}{\text{argmin}} \left[\left\| y_{t,k} - \sum_{i_1=1}^{P_1} \phi_{i_1,k} y_{t-i_1,k} - \sum_{i_2=1}^{P_2} \gamma_{i_2,k} W y_{t-i_2,-k} - \sum_{u=1}^H \sum_{i_3=1}^{P_3} c_{i_3,u,k} X_{u,t-i_3} \right\|^2 - \lambda \|\phi, \gamma, c\| \right] \quad (3)$$

2 SSTAR Forecast Error Impulse Response Function

The companion form of SSTAR was utilized to derive the forecast error impulse response function (FEIR) (4). Define $\mathbf{Y}_T$ to be a $P \times 1$ vector where entries $\{\mathbf{Y}_t \dots \mathbf{Y}_{t_p-1}\}$ are $N \times R$ observations of N time-points from R regions. $\mathbf{A}_{PR \times PR}$ an autoregressive matrix as defined in (6), $\mathbf{B}_{PR \times PR}$ a space-time autoregressive matrix as defined in (7) and $\mathbf{W}_{PR \times PR}$ a space-time diagonal weight matrix (8) with $\text{diag}(\mathbf{W}) = W$, where $W_{R \times R}$ the time-invariant weight matrices defining distance between regions as described in section 1. We deprecate exogenous variables from FEIR computations as they may be treated as a time varying intercept term.

$$\mathbf{Y}_T = \mathbf{A} \mathbf{Y}_{T-1} + \mathbf{B} \mathbf{W} \mathbf{Y}_{T-1} + \varepsilon_t \quad (4)$$

$$\mathbf{Y}_T = [\mathbf{Y}_t \quad \mathbf{Y}_{t-1} \quad \dots \quad \mathbf{Y}_{t-p_1-1}]' \quad (5)$$

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_1 & \mathbf{A}_2 & \dots & \dots & \mathbf{A}_{p_1} \\ I_n & 0 & \dots & \dots & 0 \\ 0 & I_n & \dots & \dots & \vdots \\ \vdots & & \ddots & \dots & \vdots \\ 0 & \dots & \dots & I_n & 0 \end{bmatrix} \quad (6)$$

$$\mathbf{B} = \begin{bmatrix} \mathbf{B}_1 & \mathbf{B}_2 & \dots & \dots & \mathbf{B}_{p_2} \\ I_n & 0 & \dots & \dots & 0 \\ 0 & I_n & \dots & \dots & \vdots \\ \vdots & & \ddots & \dots & \vdots \\ 0 & \dots & \dots & I_n & 0 \end{bmatrix} \quad (7)$$

$$\mathbf{W} = \begin{bmatrix} W & 0 & \dots & 0 \\ 0 & W & \dots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ 0 & 0 & \dots & W \end{bmatrix} \quad (8)$$

By defining the FEIR for some j^{th} region shock as the effect of $\varepsilon_{t,j}$ on $\mathbf{Y}_{T+h}$ [2], we yield the FEIR for SSTAR on the h^{th} horizon by recursion as in (9). $\mathbf{e}_j$ denotes a selection vector with zeros everywhere except $\mathbf{e}_{jj} = 1$.

$$\begin{aligned}
\frac{\partial \mathbf{Y}_{T+h}}{\partial \epsilon_{t,j}} &= \frac{\partial}{\partial \epsilon_{t,j}} \mathbf{A} \mathbf{Y}_{T+h-1} + \mathbf{B} \mathbf{W} \mathbf{Y}_{T+h-1} + \epsilon_{t+h-1} \\
&= \frac{\partial}{\partial \epsilon_{t,j}} (\mathbf{A} + \mathbf{B} \mathbf{W}) \mathbf{Y}_{t+h-1} + \epsilon_{t+h-1} \\
&\quad \dots \\
&\quad \dots \\
&= \frac{\partial}{\partial \epsilon_{t,j}} (\mathbf{A} + \mathbf{B} \mathbf{W})^h \mathbf{Y}_T + \sum_{i=1}^h (\mathbf{A} + \mathbf{B} \mathbf{W})^i \epsilon_i \\
&= \sum_{i=1}^h (\mathbf{A} + \mathbf{B} \mathbf{W})^i \epsilon_i
\end{aligned} \tag{9}$$

As we assume no contemporaneous relationships for the estimated model, we can simply identify α level confidence intervals for the IRF by using the bootstrap interval estimates for (4). The procedure proceeds as follows:

1. Retrieve point estimates for $\hat{\mathbf{A}}, \hat{\mathbf{B}}$ by (3)
2. Obtain bootstrap confidence intervals by block bootstrapping N samples and re-estimating $\hat{\mathbf{A}}_{\text{boot}}, \hat{\mathbf{B}}_{\text{boot}}$ at each iteration
3. Use samples obtained from Step 2 to construct the sampling distributions $\hat{\mathbf{P}}_{\mathbf{A}}, \hat{\mathbf{P}}_{\mathbf{B}}$
4. Retrieve the FEIR intervals by plugging in α and $1 - \alpha$ sampled values, $\hat{\mathbf{A}}_{\alpha}, \hat{\mathbf{B}}_{\alpha}, \hat{\mathbf{A}}_{1-\alpha}, \hat{\mathbf{B}}_{1-\alpha}$ into (9).

3 SSTAR Generalised Impulse Response Function

We modified Pesaran and Shin's (1998) [3] procedure to the SSTAR to obtain the generalised impulse response functions (GIRF). The GIRF is defined as the difference of conditional expectation of the forward forecast $\mathbf{y}_{t+j}$ given an one time shock δ_i occurs in series j given the information set Ω_{t-1} .

$$GI(j, \delta, \Omega_{t-1}) = E[\mathbf{y}_{t+j} | \epsilon_{it} = \delta_i, \Omega_{t-1}] - E[\mathbf{y}_{t+j} | \Omega_{t-1}] \tag{10}$$

The SSTAR (4) has the VMA(∞) form required for computation of GIRF after deriving the companion SSTAR form for the specification. $\mathbf{G}_i \mathbf{X}_i$ denotes the companion form matrix of exogenous variables irrelevant to GIRF calculations.

$$\mathbf{Y}_t = \sum_{i=0}^{\infty} (\mathbf{A} + \mathbf{B} \mathbf{W})^i \epsilon_{t-i} + \sum_{i=0}^{\infty} (\mathbf{G}_i \mathbf{X}_i)^i \tag{11}$$

We detail the full computational procedure to compute GIRF for SSTAR below:

1. Obtain the error variance-covariance matrix of under L_1 penalty by adapting Fan, Guo, and Hao (2012)'s estimator [1] to the vector autoregressive case with $\hat{s}_{L,\lambda}$ number of nonzero coefficients under penalized estimation :

$$\hat{\Sigma}_{L,\lambda} = \frac{1}{n - \hat{s}_{L,\lambda}} \sum_{t=1}^T \|\mathbf{Y}_t - \hat{\mathbf{A}} \mathbf{Y}_{t-1} - \hat{\mathbf{B}} \mathbf{W} \mathbf{Y}_{t-1} - \hat{\mathbf{C}} \mathbf{X}_{t-1}\|_2 \tag{12}$$

This provides us with the approximation $\hat{\epsilon} \sim N(0, \hat{\Sigma}_{L,\lambda})$

2. Pick a one standard deviation shock for the j^{th} region $\epsilon_{it} = \delta_i = \sigma_{jj}$
3. Modify Pesaran and Shin's (1998) expression to yield the scaled GIRF for the SSTAR, where $\mathbf{\Lambda}_{PRxPR}$ is a selection square matrix $diag(\mathbf{\Lambda}) = 1$ for the first 1 to J diagonals and 0 everywhere else.

$$GI(j, \delta, \Omega_{t-1}) = \sigma_{jj}^{-0.5} (\hat{\mathbf{A}} + \hat{\mathbf{B}} \mathbf{W})^j \hat{\Sigma} \mathbf{e}_j \mathbf{\Lambda}_{L,\lambda} \tag{13}$$
