Estimation of the residence time of detrital material in Lake Mikata.

If the rainfall(R) of 100mm/day continued around this region, the residence time (T: day) of the rainfall water in Lake Mikata (Area: $A_m=3.4\text{km}^2$ and average depth: $D=1.5\text{m}$), drained from catchment of Lake Mikata (Area: $A_c=60\text{km}^2$) can be estimated by the equation below,

$$T = \frac{A_m \times D \times 1000}{A_c \times R}$$

When substituting the $R = 100\text{mm/day}$, the residence time T is 0.85 (>0.75 day). Here, setting velocity of particles in the water can be derived from Stokes law shown below;

$$V_s = \frac{D_p^2 (\rho_p - \rho_f) g}{18\eta}$$

V_s is settling velocity, D_p is the diameter of the particle. The ρ_p and ρ_f is the density of particle and water (assumed as 2.65g/cm^3 and 1g/cm^3). The g is gravitational acceleration (9.8 m/s^2) and η is the viscosity of the water ($1.138 \text{ mPa}\cdot\text{s}$ on 15°C).

Maximum $V_s(\text{m/day})$ for coming out from Lake Mikata of 1.5m depth within the residence time of 0.75 day is 2.0 m/day . Substituting these values, into the Stokes Law, we can estimate maximum D_p as $5.42\mu\text{m}$, detrital grains smaller than this value can go out from Lake Mikata and flow into Lake Suigetsu.
