## **2. CYLview structures of triplet Cu dimers 26 and 27, and singlet Cu dimer 28.**

**Figure S1.** Optimized structures of triplet Cu dimers **26** and **27**, and singlet Cu dimer **28**.

Optimized structures in Figure S1 suggest that the terminal alkynyl carbons act as bridging bonds in the triplet dimer **27** and singlet dimer **28**, and the alkynyl groups all lie in *trans* positions. When the alkynyl groups are located in *cis* positions, a triplet dimer isomer **26**, in which chlorine and alkynyl groups are simultaneously used as bridging bonds, could be obtained, whereas the corresponding singlet dimer was not located. A comparison of the energies of these dimers indicates that the relative free energy of the singlet dimer **28** is 7.6 and 8.0 kcal/mol higher than those of triplet dimers **26** and **27**, respectively.

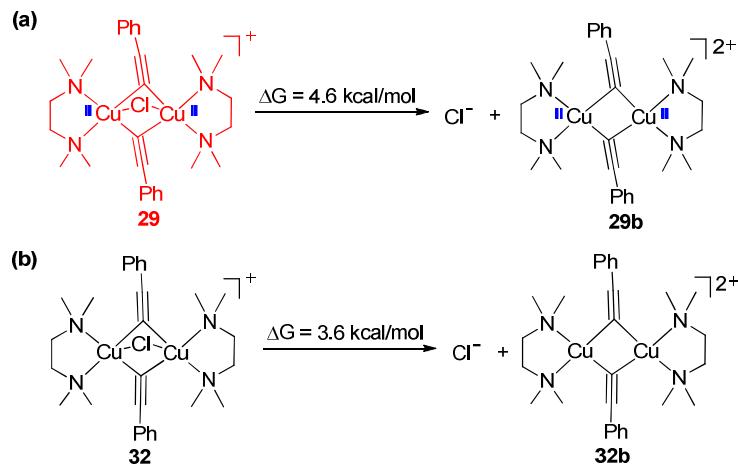

### 3. The generation of Cu(III)-acetylide **28b** from singlet Cu Dimer **28**

**Figure S2.** The generation of Cu(III)-acetylide complex **28b** from singlet Cu dimer **28**.

The 1,1-reductive elimination occurring from a Cu(III)-acetylide complex was also considered in this work. We calculated the decomposition of singlet Cu dimer **28** into a Cu(III)-acetylide complex and (TMEDA)CuCl **10**. The result shown in Figure S2 indicates that the barrier for the generation of Cu(III)-acetylide complex from complex **28** was 14.9 kcal/mol. Therefore, the formation of Cu(III)-acetylide complex is energetically unfavorable. The Cu(III) mechanism for C-C bond formation is thereby excluded.

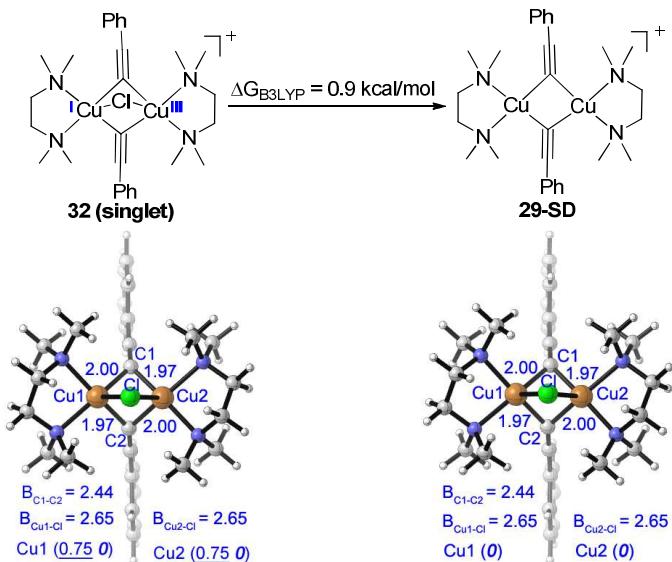

#### 4. The dissociation of another chloride from intermediate **29** and **32**

**Figure S3.** The dissociation of another chloride from intermediate **29** (a) and **32** (b).

As the dissociation of one chloride from intermediate **26**, **27**, and **28** are exergonic, the dissociation of another chloride is also calculated. Computational results suggest that the dissociation of chloride from triplet intermediate **29** is endergonic by 4.6 kcal/mol (Figure S3a). Corresponding process occurring on intermediate **32** is endergonic by 3.6 kcal/mol (Figure S3b). These data suggest that the formation of dicationic Cu species is energetically unfavorable. It is noteworthy that the transition states for chloride dissociation from **26**, **27**, and **28** are not located. This case might be ascribed to the fact that the generations of **29** and **32** are facile process.

## 5. Computational results about singlet diradical state reductive elimination

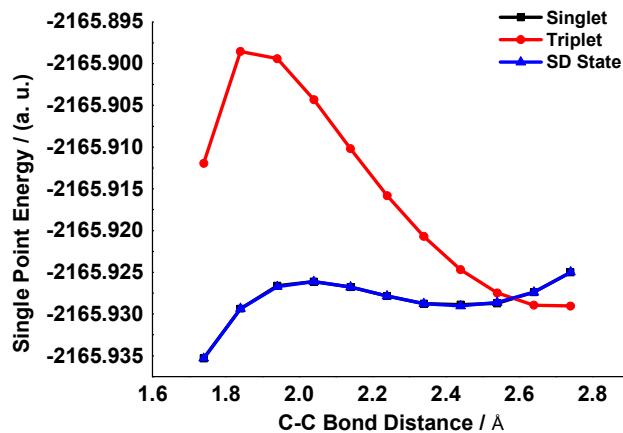

**Figure S4.** The energy and structural information of singlet diradical state complex **29-SD**.

In the manuscript, triplet cationic Cu complex **29** is proven to be the most stable intermediate for 1,2-reductive elimination. Actually, corresponding singlet diradical (SD) structure of **29** is also considered in calculation. The keyword “guess=mix” is used to obtain the SD state structure **29-SD**. However, computational results given in Figure S4 suggest that the relative free energy and structure of **29-SD** are almost the same as the singlet intermediate **32**. More importantly, calculated Mulliken spin densities of Cu1 and Cu2 in **29-SD** are zero, which imply that the spin state of complex **29-SD** is singlet. After many attempts, the obtained structures are always singlet and no SD state complex could be gained.

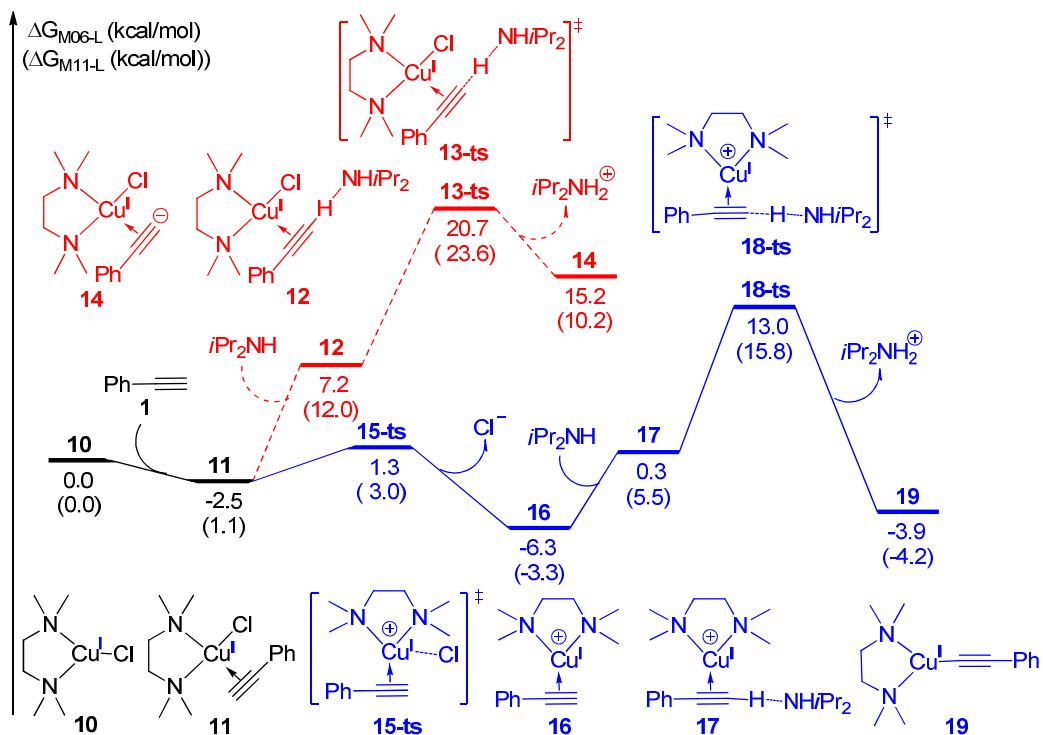

Besides, we have also optimized the SD state structure of each point in Figure 7.

Corresponding energies are added in Figure S5. The blue line stands for the energy changes on singlet diradical state potential energy surface during C–C bond formation. It is obvious that the blue line almost coincides with the black line. Moreover, Mulliken spin densities located on Cu atoms in these points are all zero. Therefore, the structures on the blue line are singlet. This result is consistent with the data given in Figure S4. All in all, the singlet diradical state intermediate cannot be located in this work.

**Figure S5.** Triplet, singlet, and singlet diradical state potential energy curves during C–C bond formation. The distance between carbon C1 and C2 in **29** was chosen as the coordinate. The step size between each point was set to 0.1 Å.

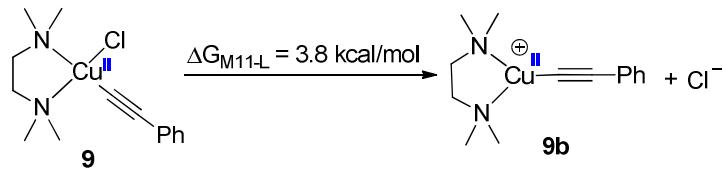

## 6. Comparison between M06-L and M11-L calculated deprotonation data

**Figure S6.** Comparison between M06-L and M11-L calculated deprotonation data.

In order to confirm the accuracy of M11-L/6-311+G(d)//B3LYP calculated data, DFT functional M06-L was employed to calculate Cu(I)-mediated deprotonation process. The same basis set is used in the solvation singlet point energy calculation. As shown in Figure S6, both M06-L and M11-L calculated data are given on the free energy profile. The comparison between these two sets of data indicates that M06-L results and M11-L results show a similar trend. Both data suggest the Cu(I) cationic catalyzed deprotonation is the favorable pathway. Moreover, although M06-L calculated data are generally lower than M11-L calculated data, the exact values are close.

## 7. The dissociation of Cl- from Cu(II)-acetylide **9**

**Figure S7.** The dissociation of Cl- from Cu(II)-acetylide **9**.

We have also calculated the dissociation of Cl- from Cu(II)-acetylide **9** using the same method and basis set. As shown in Figure S7, the dissociation of Cl- from **9** is endergonic by 3.8 kcal/mol, which indicates this process is unfavorable.
