Experimental details

Synthesis of catalysts. 30 mg of selenium powder was dissolved in 5 mL hydrazine hydrate solution, and then 30 mg of MoO₃ powder, 400 mg of NH₄F, 10 mL distilled water and 15 mL ethanol were added under stirring. Carbon fiber cloth (area: 5 cm²) was immersed into the solution above under ultrasonication for 10 min., and then the mixture was transferred to a Teflon-lined stainless steel autoclave with a capacity of 40 mL for solvent-thermal treatment at 220°C temperature for 6, 9, and 12 h, respectively. The autoclave was cooled down to room temperature naturally, and then the CMSFs were washed in distilled water and absolute ethanol under ultrasonication for 10 min, respectively, and dried in a vacuum oven at 60°C. The corresponding samples are named as CMSF-6, CMSF-9, and CMSF-12, respectively. For comparison, the additional sample was also prepared under the same conditions as those of CMSF-9, but NH₄F was not added into the reaction system. The sample was named as CMS-9.

Structural Characterization. The morphology and size of the samples were characterized by scanning electron microscope (HSD/SU70) and a FEI Tecnai-F20 transmission electron microscope equipped with a Gatan imaging filter (GIF). XPS measurements were carried out by using a spectrometer with Mg K α radiation (PHI 5700 ESCA System). The binding energy was calibrated with the C 1s position of contaminant carbon in the vacuum chamber of the XPS instrument (284.6 eV). Raman spectroscopy was performed on the Raman microscope (JY-HR800, $\lambda_{excited}$ = 532nm).

Electrochemical measurements. Electrochemical measurements were performed in a three-electrode system at an electrochemical station (CHI660D). The three-electrode configuration was adopted for polarization and electrolysis measurements, where an Ag/AgCl (KCl saturated) electrode, a graphite rod and MoSe₂-based catalysts were used as the reference electrode, the counter electrode and the working electrode respectively. Linear sweep voltammetry with scan rate of 3 mV s⁻¹ was conducted in 0.5 M H₂SO₄. For a Tafel plot, the linear portion is fit to the Tafel equation. All data has been corrected for a small ohmic drop based on impedance spectroscopy. All the potentials were calibrated to a reversible hydrogen electrode (RHE).

Table S1. Comparison of HER performance among different MoSe₂-based catalysts

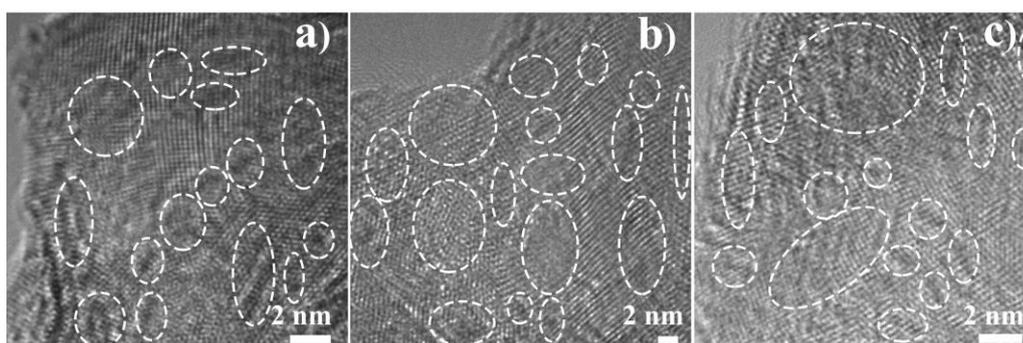

Catalyst type	Tafel slope [mV dec ⁻¹]	Exchange current j_0 [$\mu\text{A cm}^{-2}$]	Onset η [mV]	η [mV] at j_{10}	Refs
MoSe ₂ thin film	105-120	2.0	200	—	18
MoSe ₂ thin film	59.8	0.38	—	250	19
MoSe ₂ nanosheets	101	—	150	290	21
MoSe ₂ /RGO hybrid	69	—	50	115	21
MoSe ₂ nanosheets	106	—	150-260	—	12
S-doped MoSe ₂	60	—	90	—	12
MoSe _{2-x} nanosheets	98	—	170	288	13
CMSF-6	69	6.0	145	222	This work
CMSF-9	69	21.1	70	182	This work
CMSF-12	73	23.3	97	198	This work
CMS-9	76	14.4	115	206	This work

Table S2. Comparison of R_{ct} among different MoSe₂-based catalysts. Unit: $\Omega \text{ cm}^{-2}$

Catalysts	R_{ct} at 300 mV	R_{ct} at 250 mV	R_{ct} at 200 mV	R_{ct} at 150 mV
CMSF-6	3.2	9.1	133.2	380
CMSF-9	0.7	1.0	6.5	116.8
CMSF-12	0.8	1.9	7.9	244.5
CMS-9	2.0	4.9	24.4	316.5

Table S3. Comparison of R_s among different MoSe₂-based catalysts. Unit: $\Omega \text{ cm}^{-2}$

Catalysts	R_s
CMSF-6	1.5
CMSF-9	1.4
CMSF-12	1.6
CMS-9	1.7

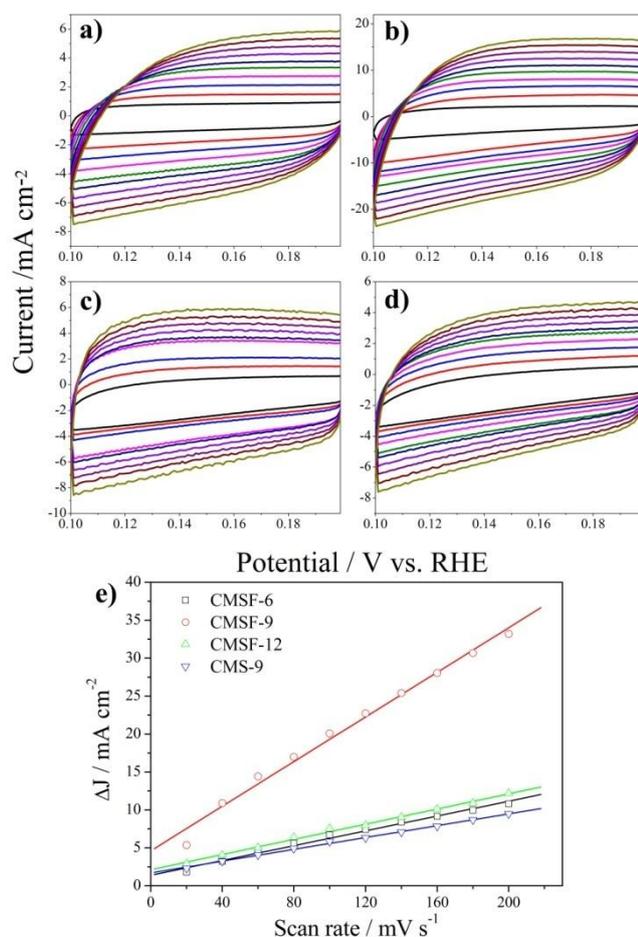

Figure S7 Cyclic voltammograms in the region of 0.1–0.2 V vs. RHE for a) CMSF-6, b) CMSF-9, c) CMSF-12 and d) CMS-9. e) The differences in current density ($\Delta J = J_a - J_c$) at 0.15 V vs. RHE plotted against scan rate fitted to a linear regression allows for the estimation of C_{dl} .

The estimation of the effective active surface area of the samples was carried out according to literature. Cyclic voltammetry (CV) were performed at various scan rates (20, 40, 60 mV s⁻¹, etc.) in 0.1–0.2 V vs. RHE region. The double-layer capacitance (C_{dl}) of various samples can be determined from the cyclic voltammograms, which is expected to be linearly proportional to the effective surface area (Figure S7 a-d). The exact determination of the surface area is difficult due to the unknown capacitive behavior of the MoSe₂ nanosheets, but we can safely estimate the relative surface areas. CV measurements were taking in the region of 0.1-0.2 V vs. RHE, which could be mostly considered as the double-layer capacitive behavior. The double-layer capacitance is estimated by plotting the ΔJ ($J_a - J_c$) at 0.15 V vs. RHE against the scan rate, where the slope is twice C_{dl} (Figure S7 e). The C_{dl} were calculated to be 24.4 mF, 73.5 mF, 25.0 mF and 19.5 mF for CMSF-6, CMSF-9, CMSF-12 and CMS-9, respectively.

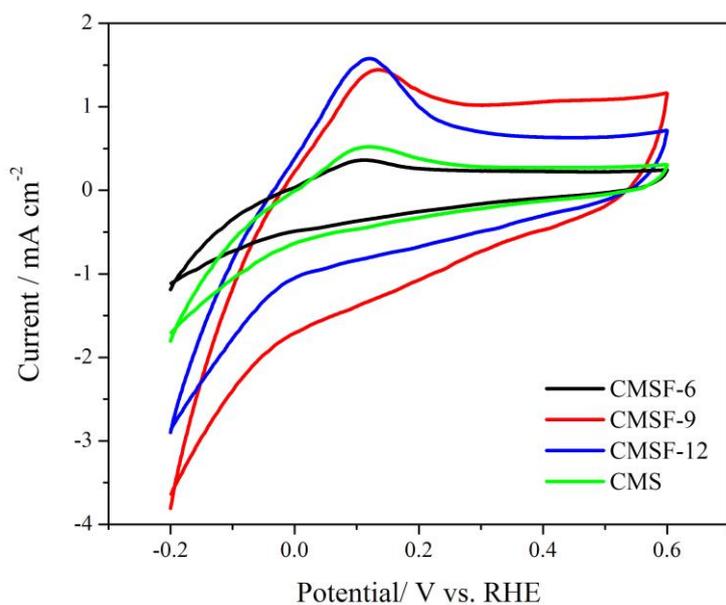

Figure S8 Cyclic voltammograms (CV) in the region of -0.2 to 0.6 V vs. RHE for our MoSe₂-based catalysts at pH=7.0. Scan rate: 50 mV s^{-1} .
