Experimental Section

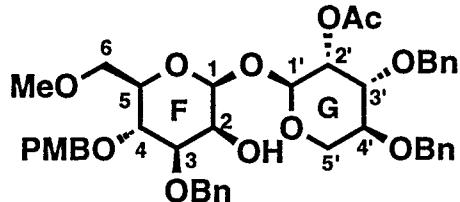

General Techniques. All reactions were carried out under an argon atmosphere with dry, freshly distilled solvents under anhydrous conditions, unless otherwise noted. Tetrahydrofuran (THF), toluene and diethyl ether (ether) were distilled from sodium-benzophenone, and methylene chloride (CH_2Cl_2) from calcium hydride. Anhydrous solvents were also obtained by passing them through commercially available alumina columns. Yields refer to chromatographically and spectroscopically (^1H NMR) homogeneous materials, unless otherwise stated. Reagents were purchased at highest commercial quality and used without further purification unless otherwise stated. Reactions were monitored by thin layer chromatography carried out on 0.25 mm E. Merck silica gel plates (60F-254) using UV light as visualizing agent and 7% ethanolic phosphomolybdic acid or *p*-anisaldehyde solution and heat as developing agents. E. Merck silica gel (60, particle size 0.040-0.063 mm) was used for flash column chromatography. Preparative thin-layer chromatography (PTLC) separations were carried out on 0.25, 0.50 or 1 mm E. Merck silica gel plates (60F-254). NMR spectra were recorded on Bruker AMX-600 or AMX-500 instruments and calibrated using residual undeuterated solvent as an internal reference. The following abbreviations were used to designate the multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, b = broad. IR spectra were recorded on a Perkin-Elmer 1600 series FT-IR spectrometer. Optical rotations were recorded on a Perkin-Elmer 241 polarimeter. High resolution mass spectra (HRMS) were recorded on a VG ZAB-ZSE mass spectrometer under fast atom bombardment (FAB) conditions with NBA as the matrix. Melting points (m.p.) are uncorrected and were recorded on a Thomas Hoover Unimelt capillary melting point apparatus.

Typical procedure for the synthesis of disaccharides. Preparation of compound 7.

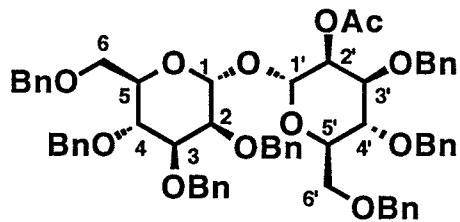

In a 50 mL Schlenk-tube were added diol **3** (91 mg, 0.20 mmole), $(n\text{-Bu})_2\text{SnO}$ (60 mg, 0.24 mmol) and anhydrous methanol (5 mL) and the mixture was brought to a gentle reflux under argon. After the solution turned clear, refluxing was continued for an additional 2 h, before cooling to ambient temperature and concentration under reduced pressure. The residue was azeotroped with benzene (2 mL) before addition of imidate **3** (85 mg, 0.13 mmol) in benzene (2 mL). Removal of the solvent under reduced pressure followed by further drying by azeotroping with benzene (3 x 2 mL) and finally applying high vacuum (1 mbar, 0.5 h) gave an amorphous residue which was dissolved in anhydrous ether (1.0 mL). The solution was cooled (0 °C) and TMSOTf in ether (0.13 mL, 0.5 M) was added dropwise. The reaction mixture was allowed to warm slowly to room temperature and stirred until TLC analysis indicated complete disappearance of imidate **4** (ca 48 h). Triethylamine (0.2 mL) was added, followed by a saturated aqueous solution of NaHCO_3 (10 mL) and EtOAc (30 mL). The layers were separated and the organic phase was extracted with brine (5 mL), dried (MgSO_4), filtered, and concentrated *in vacuo*. Purification of the residual oil on silica gel (ether/hexanes, 1:2→1:1→2:1) afforded compounds **7** (81 mg, 66%) and **9** (17 mg, 9%).

Typical procedure for the synthesis of trisaccharides. Preparation of compound 9.

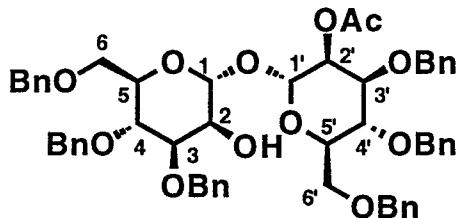

The procedure as described above for the synthesis of disaccharides was followed, except for the use of 2.2 equiv of glycosyl fluoride **8** instead of trichloroacetimidate **4**. Yield of **9** (84%).
